The other thyroid disease with which physicians are familiar is exophthalmic goitre. I do not propose to enter into an elaborate discussion of this disease, but I would draw attention from the clinical point of view to the rapid pulse, the easily embarrassed breathing, and the nervous instability familiar in this disease, and present also in the two cases I have described after operation. With regard to its pathology many views have been held, but I wish to emphasise here Murray's view, put forth at a discussion of the British Medical Association in August, 1896.[2] Murray compares the thyroid gland in exophthalmic goitre with the changes which occur experimentally to compensate for the removal of part of the gland. The most important changes in this hypertrophied gland are (1) the formation of the new alveoli; (2) folding of the wall of the alveoli in some places, so that the internal surface of the epithelium is increased in extent; and (3) a change of the epithelial cell from a cubical to a columnar form. Compared with a normal thyroid gland we have here the appearances presented by a gland which is working at high pressure. In exophthalmic goitre there is found an increase of the

[2] Brit. Med. Jour., Oct. 3rd, 1896.

Digitized by Google

secretory tissue, for the number of alveoli is increased, and the epithelial cells themselves, instead of being cubical, are columnar. It is evident that the thyroid gland in exophthalmic goitre has a strong resemblance to a portion of gland which has undergone compensatory hypertrophy, and which is in a condition of over-activity. We know very little about the nature of the secretion of the thyroid gland in exophthalmic goitre. It is probable that it is altered in quality as well as in quantity. Anyhow, there is a satisfactory anatomical basis for considering the symptoms as due to an over-activity of the gland. Clinical evidence also gives support to this view. Improvement occurs in many cases when as a result of operation the secretory activity of the gland is diminished—i.e., either by excision of part of the gland or by ligature of some of its vessels.

In an article in the *Practitioner* for November, 1896, Mr. Carless reviews the treatment of exophthalmic goitre. In considering the thyroid theory of the disease he states that the treatment by belladonna succeeds by diminishing the thyroid secretion. Thyroid given in moderate doses has sometimes produced some of the features of exophthalmic goitre, but this may possibly be due to toxic products of putrefaction. If given in exophthalmic goitre it increases for a time the cardiac and nervous symptoms. In discussing the operative treatment of the disease he refers to the symptoms which I have described as follows: "The death-rate amounts to not less than 12 per cent. This is due in a measure to a curious condition which not infrequently supervenes after an apparently clean and successful operation. All goes well for a few hours and then suddenly the temperature rises to 103° or 104° F., the pulse runs up to a high rate, the urine is loaded with albumin, the patient becomes delirious or comatose, and finally dies perhaps within fifteen hours of the operation." This description coincides in the main features with the description I have given. With regard to the cause Mr. Carless adds that "it has been suggested that it is an excessive secretion of the thyroid secretion brought about by handling the tumour or by a stimulation of the secretive activity by the anæsthesia. It has occurred after the simplest cases as well as after the more serious ones, but curiously has never been noticed after dealing with simple goitres." The last statement can scarcely hold true any longer, and though I have not found records of published cases of these symptoms occurring after operation on simple goitre I have heard of such cases. The clinical effects of giving an excess of thyroid also support this view. For example, in a case described by Murray a woman took by mistake ninety-two grammes of thyroid gland in eleven days. The symptoms she suffered from were tachycardia, rapid respiration, exophthalmos, tremor, rise of temperature, and insomnia, symptoms analogous to the condition to which I have drawn attention.

In the two cases above described which showed symptoms cysts were removed from the thyroid gland and a considerable quantity of the fluid escaped into the wound. Hence it would easily be absorbed by the lymphatics, and this, I may say, is the way in which it has been shown that the thyroid secretion normally is conveyed from the gland into the circulation. I therefore submit that the symptoms of exophthalmic goitre, of cases where thyroid has been administered in excess medicinally, and of cases where during operation the contents of a cyst have been emptied into the wound, bear an intimate relation to one another, and that they are due to an excess of thyroid secretion in the circulation. Further, in support of this view, and against the view that the symptoms are due to a want of thyroid, I would point out that in these cases only unhealthy thyroid is removed, that the symptoms are independent of the amount removed or left behind, that they occurred in Case 4, where only a cyst was removed and plenty of thyroid was left, and especially that they occur in exophthalmic cases where only one lobe is removed.

[The writer then referred to Mr. Horsley's explanation of the symptoms in Case 1 as being due to lack of thyroid secretion, to which cause also he attributes the symptoms of exophthalmic goitre. He proceeded to describe fully the symptoms of cachexia strumipriva.]

The subject can only be solved by experimental investigation and by accurate clinical observation coupled with a more complete publication of unsuccessful cases. I submit that none of the important researches which I have quoted offers any fundamental objection to the following propositions: (1) that the symptoms to which I have been drawing attention—namely, rapid pulse and respiration and restlessness—are analogous to those of exophthalmic goitre; (2) that they are due, as in that complaint, to the absorption by the lymphatics into the circulation of a perverted secretion of the thyroid, not to the absence of normal thyroid; and (3) that in the cases where these symptoms have been most frequently seen after thyroidectomy — namely, after operation for exophthalmic goitre — it is due to squeezing out some secretion while handling the tumour; and that in the cases I have described it entered by the cyst being ruptured into the wound.

[The writer concluded by urging the importance of guarding against these serious symptoms by taking as much care to prevent the contents of a thyroid cyst from entering the wound as a surgeon takes in dealing with a fluid tumour of the abdomen. Should the symptoms arise the hypodermic injection of morphia, he considers, seems to promise the best results.]

Gloucester-terrace, W.

AN UNUSUAL CASE OF WOUND OF THE HEART; RECOVERY.

BY SAMUEL PRIOR, M.B., C.M. GLASG.,
ASSISTANT PHYSICIAN TO THE WOODILEE ASYLUM, LENZIE, GLASGOW.

WOUNDS of the heart are serious both from the immediate danger of wounding the heart itself and from the complications that are apt to arise. Recovery or even partial recovery is all the more satisfactory. The following case, ending in complete recovery, may be interesting.

The patient, a man aged forty-three years, was an epileptic whose mental decadence was not much advanced. The fits were infrequent and usually slight—of the character of *petit mal*—though he had occasionally well-marked convulsions. He was a confirmed pickpocket and hoarded up pins, nails, pieces of wire, &c., which were, as a rule, used by patients for cleaning tobacco pipes. In the year 1890 he had shown a strong suicidal tendency by inflicting a deep wound on his neck. He is a type of patient well known in asylums, requiring careful and strict supervision day and night. Last April he made another suicidal attempt. He cunningly chose the time when the patients were getting up and the attendants were very busy for this determined though unsuccessful attempt. The attendant in charge in the sick-room observed the patient doing something unusual, and on removing the bed-clothes was astonished to find an iron pin projecting from the chest in the region of the heart. The exact situation was 1¾ inches below and 1 inch internal to the left nipple. This pin was directed slightly upwards and inwards. It moved vigorously with every beat of the heart and travelled about an inch upwards and downwards every time. On examination the pin was felt to be firmly embedded in the wall of the heart, which was felt tugging at the inner end of the pin. Removal of this peculiar foreign body was not undertaken without some misgivings as to the result. The pin was rotated and gently withdrawn; the part within the chest measured 3 inches, making a total length of 4 inches of $\frac{3}{16}$-inch iron wire. The patient was collapsed; he had a small, feeble pulse, 64 per minute; respiration was shallow, 24 per minute; and the skin was cold. There was practically no hæmorrhage from the wound. No external hæmorrhage appeared subsequently to this, and there were no signs of effusion of blood or serum into the pericardium. The patient kept his eyes closed. He did not resist an examination of the pupils, which were dilated and reacted but slightly to light. When spoken to he would not answer. I thought he was conscious of all that was said, and subsequent events made this almost certain. The wound was dressed antiseptically, and there was no visible suppuration at any time. On the day following the infliction of the wound there was some subcutaneous emphysema round the wound. The physical signs of pneumothorax appeared, but this and the emphysema disappeared again in twenty-four hours. The temperature, pulse, and respiration rates rose to a maximum thirty-six hours after the wound was made. The records were as follows: at 7 P.M. the temperature was 100·8° F., the pulse was 112, and the respiration was 36; at 9 P.M. the temperature was 101·0°, the pulse was 109, and the respiration was 32; at 11 P.M. the

Digitized by Google

temperature was 101·0°, the pulse was 105, and the respiration was 38. The temperature remained slightly febrile for a week and then became normal. The patient would not take food or drink for four days, and seemed indifferent to everything about him. On the fourth night he asked for a drink of water. The following day he looked round the room several times when he thought no one was watching him. He asked why he was kept in bed and wished to get up. Several pieces of wire were found in his bed, showing that he was still occupied with suicidal projects. He was removed to another bed, it being supposed, and rightly so, that he had concealed these in the wire mattress. A handful of pieces of wire, needles, pins, &c., was taken out of the mattress. He was excessively annoyed at having his bed changed and the wire, &c., removed. He told one of the attendants he "hadn't succeeded yet, but would try again and succeed." His appetite soon returned and he recovered his usual health. Numerous pulse tracings were taken. Soon after the pin was removed the tracing showed a low tension pulse with almost full dicrotism and slight irregularity. On the third day the tracing showed a better tension pulse; the dicrotism was nearly gone. On the fourth day there was still some dicrotism; the tracings showed great amplitude of the percussion wave. Normal tracings were obtained on the succeeding days. There are now (nearly six months after) no signs of pericardial adhesion. The only evidence left of the injury is a reddish linear scar half an inch long, directed downwards and outwards.

It is rather surprising that such a thick and dirty piece of wire produced no suppuration or irritation of the pericardium. The pin must have entered at least two inches into the wall of the left ventricle, but did not enter the cavity of that ventricle. The patient seemed rather surprised and ashamed at his failure. Although kept under the closest supervision day and night he declares his intention plainly of "trying to manage it yet." Life for him has no attraction—it is indeed a weariness to the flesh; he has reached a point where "the terrors of life outweigh the terrors of death."

Glasgow.

ON THE SURGICAL TREATMENT OF SPASTIC PARALYSIS IN CHILDREN.

BY J. JACKSON CLARKE, M.B. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON AT THE NORTH-WEST LONDON AND CITY ORTHOPÆDIC HOSPITALS.

WHEREVER many disabled children are seen a certain proportion of them will be found to be suffering from spastic paralysis. Though recognised from the earliest times the affection was first systematically described by the English orthopædic surgeon, Little, who rightly ascribed the majority of cases to superficial lesions of the cerebral convolutions resulting from meningeal hæmorrhage induced by the pressure of the maternal pelvic bones on the fœtal skull. It is naturally commonest in first-born children and is usually congenital. Some cases, however, are not congenital, but arise in infancy from thrombosis of the superficial cerebral vessels during the course of fevers, such as measles, scarlet fever, and influenza. All grades of the affection are met with. There may be muscular rigidity of the neck and trunk as well as of the limbs, or only the lower limbs may be affected. The intellectual functions may be totally destroyed or completely intact. In the latter case it has been supposed that the affection is of spinal origin, though there is no satisfactory proof that this invariably holds good. As an introduction to the surgical aspects of spastic paralysis one of these slighter cases may be briefly considered, a case in which the intellect is unaffected and the spasm is limited to the muscles of the leg with resulting talipes equinus, equinovarus, or equino-valgus. Electricity and massage have been tried till the parents of the child have grown weary and the uselessness of these measures has become obvious. Recourse has then been had to retentive apparatus in order to try to effect a gradual correction of the deformity. Hope is awakened, and with patient endeavour the apparatus is given every chance of effecting its purpose. But after months or years of perseverance the uselessness of retentive apparatus alone becomes evident. It is uncomfortable and wearisome to the little patient, increasing the spasm of the stronger muscles, and in this way rather impeding than helping progression. And whenever the apparatus is left off for a moment the deformity at once returns with, if anything, greater rigidity than ever. At last, with reluctance and sometimes with but little confidence, operative treatment is suggested, and the parents of the child accept it as a last desperate chance. If the operation is done thoroughly, every resisting tendon being completely severed and the limb fixed at once in an over-corrected position and so left for four or five weeks, it is found that at the end of this time the tendency to return to the deformity is greatly diminished and walking is again possible to the patient, and, if the latter is intelligent, by exercise of the will the tendency to deformity may soon be entirely overcome, so that retentive apparatus may be dispensed with in the day and at night only a light and simple shoe may be required to render the cure a permanent one.

If a case of infantile paralysis is compared with one of spastic paralysis, a marked contrast may be observed. Infantile paralysis is caused by destruction of the cells of the anterior cornua of the spinal cord; spastic paralysis is attributable to partial disablement of the cells of the motor cortex or to partial blocking of the pyramidal tracts. In infantile paralysis massage and Faradaism in the early stages help the recovery of any muscular fibres of which the nutritive nerve cells have not been completely destroyed; in spastic paraplegia massage is of no use apart from complete tenotomy. In infantile paralysis suitable apparatus prevents the occurrence of deformity; in spastic paralysis the deformity is only overcome by the use of much force and at the cost of some distress to the patient. In deformity due to infantile paralysis tenotomy, &c., are only employed to bring the limbs into workable shape and, save in the very slightest cases, the retentive apparatus must be worn for the rest of the patient's life; in spastic paralysis efficient tenotomy, by weakening the muscles the persistent over-action of which produces the deformity, tends to restore the balance of muscular power, and in most cases this may be so far successful that retentive apparatus can be dispensed with.

Lorenz,[1] who has recently published an important series of observations on this topic, attributes the good effect of thorough tenotomy in spastic cases, to the shortening of the bellies of the tenotomised muscles, so that their range of action is diminished. In severe cases of spastic contraction of the knee Lorenz recommends excision of from one inch to one and a half inch of the tendons of the biceps, semi-tendinosus, and semi-membranosus muscles; and even after such tenectomies and subsequent straightening of the knee Lorenz has never observed a failure of union in the widely-separated ends of the tendons. Thus, after an ordinary tenotomy failure of union need not be feared. For the marked adductor spasm, which, by causing the knees to press against each other, is often such a serious hindrance to progression, Lorenz has found that in mild cases forcible stretching of the adductors combined with manipulation is successful, in more severe cases subcutaneous tenotomy answers, whilst in the most pronounced cases he has successfully excised a section of the obturator nerve—an operation of some difficulty in the adducted position of the limb.

Indications for operative treatment.—Before deciding to undertake the operative treatment of any case various factors have to be weighed. In the first place, the condition of the intellectual faculties must be considered. Often the mind is altogether vacant and in such cases it is not worth while to rectify malpositions. Sometimes the condition is complicated by bilateral athetosis (general chorea) and this may be taken as a distinct contra-indication. Epilepsy is a somewhat rare complication and would also be an argument for non-interference. General rigidity renders improvement of the condition of the legs of but little service to the patient. In diagnosis the cases of infantile cerebral degeneration with symmetrical changes at the macula, first observed by Waren Tay and recently described by Kingdon and Risien Russell,[2] must be borne in mind. Such cases begin in infancy and end fatally about the end of the second year. They are marked by progressive paralysis and some rigidity.

The paraplegic forms of spastic paralysis are the more

amenable to treatment, especially when the chief part of the disability consists in spastic club-foot. Such cases give complete satisfaction to all concerned.

Old Cavendish-street, W.

A CASE OF PUERPERAL ECLAMPSIA SUCCESSFULLY TREATED BY CHLORAL AND BROMIDE OF POTASSIUM WITH INHALATION OF CHLOROFORM.

BY WILLIAM FREDERICK GARDENER, M.R.C.S. ENG., L.R.C.P. LOND.

I WAS called on Dec. 6th, 1896, at 4.45 P.M., to see a woman who had engaged me to attend her in her confinement about that date (Dec. 8th to 15th). She was forty-one years of age, and this was her first pregnancy. On arrival I found her dressed and seeming very dull. It was said that she had been complaining of "her head" and suddenly went off into some kind of fit, her features being convulsed and blackened. The case seeming like puerperal eclampsia she was at once removed to bed. A soap-and-water enema had been given in the morning which had acted slightly. At 5.15 the patient was seized with a second fit, in all respects typical of puerperal eclampsia. Three grains of calomel were placed on the back of the tongue and followed by 20 grains each of chloral hydrate and bromide of potassium. Most of the calomel was swallowed and the whole of the mixture. At 5.50 a third convulsion occurred which was cut short by administration of chloroform vapour. At 6.50 another fit was similarly treated, the inhalation of chloroform being prolonged for the purpose of making a vaginal examination. The os was found to be dilated to the diameter of a little less than half an inch. At 8 o'clock $\frac{1}{10}$ gr. pilocarpine hydrochlorate was injected subcutaneously. In response to repeated inquiries the patient complained of sickness. At 8.45 and 9.32 the fits recurred. By 9 P.M. the os had dilated very slightly. At 10.30 the patient commenced to moan, her eyes opened, and lateral nystagmus became visible with turning of the head and eyes to the left. A few whiffs of chloroform removed all these symptoms and staved off another convulsion, as in this way the previous ones had commenced. At 11.5 P.M. and 12.55 A.M. the nystagmus returning convulsions were again prevented by a prophylactic use of chloroform. Every three hours a nutrient enema of beef-tea and milk was administered containing twenty grains each of bromide of potassium and chloral hydrate. At 9.15 P.M. urine had been passed into the bed and at 10.45 P.M. the bowels had commenced to act. At 2.25 A.M. on Dec. 7th a convulsive attack again seized the patient, the first not prevented since 9.32 the previous evening. At 4.25 A.M. the temperature was 103° and the pulse was 108. At 10.20 the temperature was 100° and the pulse 118. At 12.30 P.M. the first specimen of urine was obtained, being drawn off by catheter; it was "porter-coloured" and yielded five-sixths albumin. In consultation with Mr. Soltau Eccles, of Norwood, it was decided to leave the case to nature unless there should be any return of the convulsive seizures. The pains were then becoming fairly regular and the os was very slowly dilating. There were no more fits. The mixture of bromide of potassium and chloral hydrate was given in small enemata of milk and beef tea every four hours. The pupils remained contracted, and the patient complained occasionally of great pain in the head, but the nystagmus and twitching of the muscles were absent and the bowels acted freely and often. By 4 o'clock the amount of albumin present had diminished to one-sixth, lessening slightly towards evening. At 11 o'clock the fœtus was born without any very strong pains. It was stillborn, and had apparently been dead some days. At 2 A.M. on Dec. 8th the temperature had fallen to 99·4°, and at 8 o'clock to 97·2°. From this date to Dec. 19th there was considerable variation of temperature from 97° to 102°. The urine contained from one-tenth to one-eighth albumin up to this date, then slowly cleared off, till early in January only a very faint trace remained. Very severe headaches were present during the whole time, for which a variety of drugs were tried, ammonium chloride giving the best results. A mixture of acid tartrate of potash and digitalis was given for some weeks, with 40 gr. of pulv. jalapæ co. at night.

The great interest in this case was the extraordinary ease with which the fits were arrested by chloroform inhalation. One hundred grains each of chloral hydrate and potassium bromide were retained by the mouth and rectum.

Sydenham.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF TUBERCULOUS DISEASE OF THE BLADDER TREATED BY SUPRA-PUBIC CYSTOTOMY AND CURETTING.

BY EDWARD COTTERELL, F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, LONDON LOCK HOSPITAL, &C.

I WAS consulted in the spring of 1895 by a man aged thirty-two years who complained of great irritability of the bladder both by day and by night. There was pain in the hypogastric region, in the perineum, and in the middle of the penis during and after micturition, and occasionally there was stoppage of the stream. Now and then a few small clots of blood passed after micturition. These symptoms had been coming on for some ten or twelve months and were becoming gradually intensified. The patient was losing flesh; he looked ill and altogether appeared to be in a very unsatisfactory state of health. The urine was alkaline, of specific gravity 1012, and contained a large amount of muco-pus, but tubercle bacilli were not detected in the deposit after centrifugalisation. The prostate was slightly tender, but was not nodular or perceptibly enlarged. The testicles were free from evidences of tuberculous disease. Cystoscopic examination showed that the bladder was markedly trabeculated, and a small ragged ulcer was detected just below the mouth of the right ureter. Upon June 23rd, 1895, I performed supra-pubic cystotomy and thoroughly curetted the ulceration, after which the raw surface was freely burnt with Paquelin's thermo-cautery. The after history of the case presented nothing unusual. The wound healed within a month, and the urine gradually became acid and free from pus and mucus. After the wound had healed the irritability of the bladder was found to have disappeared completely, but owing to the contracted state of the bladder micturition for some time was a little more frequent than is usually the case; but gradually this condition improved and approached the normal standard. In the following December the patient was apparently quite well. The urine was acid, with a specific gravity of 1028. There was no irritability of the bladder by day or by night. There was no pain, and altogether the general as well as the local condition had much improved since he came under my care.

I am induced to add the notes of this case to those on the same subject which have previously appeared in THE LANCET as a further contribution to the modern surgical treatment of tuberculosis affecting the bladder. At the present time (September, 1897) the patient is quite well in health. He has had no urinary symptoms or trouble whatever since convalescence from the operation has been established, so that the case appears to promise well for the future.

West Halkin-street, S.W.

NOTE ON A CASE OF DEATH FROM LIGHTNING STROKE.

BY C. F. GLINN, M.R.C.S. ENG., L.R.C.P. LOND.

ON April 28th, 1897, about 4 P.M., during a thunderstorm of unusual severity, I was called out to see a farmer, aged fifty-four years, who, it was stated, had apparently been struck dead by lightning about half an hour previously. On my arrival I found the man dead and lying on the kitchen floor, where he had been placed when brought in. I was told that at the commencement of the storm he had said to his wife that he would go out in the field just behind the house to-

Digitized by Google

drive in some cattle to shelter. Two or three minutes later his son, aged sixteen years, came in by the front entrance and said he had had a narrow escape from the lightning, as "he had felt it strike along the front of his leggings, and it had made his legs feel numb-like up to his knees." An older son then went out to see if his father was safe, and on passing through the gate of the yard saw his father lying on the ground about thirty yards from the house. He went up to him and found that he was dead; he was lying at full length with his face downwards, his right hand in his trousers pocket. A small pool of blood was under his head, his hat (a black felt one) was lying about a yard away, and was torn to pieces. Both cloth leggings were torn almost from top to bottom and a small piece of one was lying near. On proceeding to examine the body I found over the situation of the upper anterior angle of the left parietal bone a wound the size of a penny, the soft structures of which were quite disorganised down to the bone, but the bone itself appeared uninjured. The hair round the wound was burnt and a good deal of blood was coagulated in the hair around. From the direction of this wound a red line of hyperæmia about a quarter of an inch broad could be distinctly seen running in an oblique direction down the neck and over the middle of the clavicle to the epigastrium. The hair of the neck and body was burnt and singed along this line and there was a strong smell of burning when the clothes were removed; at the epigastrium this line merged into a diffused hyperæmia which involved the whole of the lower part of the trunk and both thighs; the hyperæmia ended at the knees, but a red line similar to that above described ran down the outer side of the right leg and foot to the little toe (the inner surface of the right boot was torn along a line corresponding to this). On the under surface of the left foot just below the instep was a fresh bleeding wound the size and shape of a threepenny-piece. There were two bullæ about the size of a man's thumb in the left groin. On removing the body upstairs the wound on the head began bleeding again so freely that a considerable pool of blood (about half a pint) was formed on the floor; this appeared to indicate an abnormally fluid state of the blood. The face was very livid. There was no watch or any other article whatever found in the pockets. There was an iron wire round the brim of the hat, apparently used for stiffening purposes; the hat itself was torn to pieces, leaving this exposed.

Hatherleigh, North Devon.

A NOTE UPON THE RELATIVE VALUE OF SILK AND CATGUT AS MATERIAL FOR SUTURES.

BY A. BOUILLON, M.D., C.M.

ON Aug. 11th, 1897, I was called to attend a farmer whose right arm had been caught in a mill. The limb from the fingers to the elbow was all crushed or bruised. I had to perform disarticulation at the elbow, and fortunately there was sufficient skin on each side, so I sutured it with antiseptic catgut and silk thread in alternate stitches. On Aug. 15th I went to see my patient. To my great surprise the man was sitting and smoking with other members of the family. I removed the bandage, and everywhere where I had sutured with silk the skin was white and natural and the edges were firmly adherent as if it had been merely a slight cut; but at the gut sutures the edges of the skin were slightly separated and pus was oozing out where the stitches passed through the skin and the skin was red and swollen. The conclusion to be drawn from this is that the best ligature to use in amputation is silk.

Matane, Canada.

THE SEWAGE OF BRISTOL.—The sub-committee of the sanitary committee appointed to inquire into the nuisance arising from the pollution of the River Avon and the New Cut by the discharge of the Bristol sewage have unanimously resolved to ask their committee to report to the Bristol Town Council that the best way of dealing with the evil is to carry the sewage into the Bristol Channel by the plan of extending their main sewers. Although expensive it may be anticipated that this plan will receive the confirmation of the sanitary committee at their next meeting.

GUY'S HOSPITAL.

A CASE OF SARCOMA OF THE UPPER JAW IN A WOMAN TWENTY YEARS OF AGE; EXCISION; RECOVERY.

(Under the care of Mr. CLEMENT LUCAS.)

MYELOID sarcoma of the upper jaw in young adults is by no means rare, and its starting point is almost always the alveolar border of the bone. In a very large proportion of the cases there has been extensive caries of the teeth on the affected side, and the association is sufficiently constant to justify the assumption that there is a causal relation between the caries and the sarcoma. In the following case the caries of the teeth had been extensive and of long duration.

A woman, aged twenty years, was admitted into Guy's Hospital on May 19th, 1897, complaining of a swelling in the mouth. The patient's health had always been good, but she had for years suffered much from her teeth. About last Christmas (1896) she noticed that her right cheek was becoming more prominent, and about three weeks before her admission to the hospital she found that the gum of the upper jaw on the right side was swollen and this swelling had increased rapidly. On admission it was seen that the alveolar border of the right superior maxillary bone was the seat of a swelling extending from the middle line outwards for about one and a half inches. The anterior part of the alveolar process was pushed forwards, obliterating the naso-labial fold, and a great portion of the process was loose, the right central and lateral incisor teeth moving with it. The growth extended also backwards on to the hard palate for about an inch. The surface of the growth was uneven, firm and elastic to the touch, and pink in colour; no egg-shell crackling could be made out. The right cheek was somewhat more prominent than the left. On May 24th the patient was anæsthetised and an incision was made through the upper lip and round the right ala of the nose; the lip and cheek were dissected off the right superior maxilla and the bone was sawn through just to the right of the septum and also immediately below the orbit and at its attachment to the malar bone. The superior maxilla was then wrenched away, leaving the orbital plate, and the hæmorrhage having been stopped the wound was dusted with iodoform and tannin, the lip was drawn together with two harelip pins, and the edges of the incision were sutured with horsehair. The whole was then dressed with a "sealed" dressing of iodoform and collodion on gauze. On examination of the portion of bone removed it was seen to be much softened and infiltrated by the growth; when examined microscopically it was found to be a giant-celled sarcoma. The mouth was washed out frequently with warm water and gargled with a solution of resorcin (ten grains to the ounce). On the 27th the sealed dressing was taken off and all the stitches were removed together with the harelip pins. The part was re-sealed with iodoform and collodion painted on sal alembroth gauze. The dressing was finally removed on June 4th, when it was found that the face incisions had all healed by first intention. The patient left the hospital on June 6th convalescent.

BIRMINGHAM GENERAL HOSPITAL.

A CASE OF ACUTE GENERAL SUPPURATIVE PERITONITIS TREATED BY LAPAROTOMY.

(Under the care of Mr. LEONARD GAMGEE.)

THE treatment of acute general suppurative peritonitis is exceedingly unsatisfactory. An expectant treatment, with or without the use of drugs, may in a few—a very few—cases

Digitized by Google

be followed by recovery; but a doubt must always exist as to the peritonitis having been general, for the probability is decidedly in favour of its having been only partial, localised by the formation of adhesions. The results of surgical interference are hardly more satisfactory; cases do occur in which energetic flushing and draining of the peritoneal cavity prove successful in saving the patient's life, but unfortunately these cases are quite exceptional. For the usual fatal result several adequate causes can be assigned. In the first place the general condition of the patient is so grave that the additional shock of a laparotomy, slight though that shock may be, is sufficient to lead rapidly to a fatal result, but another cause is the practical impossibility of washing away all the exudation; some of it is very adhesive, and cannot be removed by a stream of water; and, lastly, as has been pointed out by Mr. C. B. Lockwood in his lectures on Traumatic Infection at the Royal College of Surgeons of England,[1] at a very early period of the disease the micro-organisms penetrate the epithelial lining of the peritoneum and thus would be quite undisturbed by the most thorough flushing of the peritoneal cavity. At the Carlisle meeting of the British Medical Association in 1896, in a discussion on Appendicitis, Mr. Mitchell Banks mentioned that he had never seen a patient's life saved if general perforative peritonitis had occurred, even though the peritoneal cavity had been thoroughly washed out.[2] It is probable that the variety of micro-organism causing the peritonitis has much influence on the ultimate result. The utility of judicious flushing of the peritoneal cavity in certain cases is amply borne out by the very interesting case under the care of Mr. Gamgee which is recorded below.

A girl, aged sixteen years, was admitted into the General Hospital, Birmingham, on Jan. 1st, 1897. Fourteen days before admission the patient, while engaged in household duties, felt a sudden severe pain over the lower half of the abdomen. With the onset of the pain she became faint and had to lie down. Her temperature rose to 102° F. At the end of eight days from this time the pain had gone and her temperature was normal. On Dec. 30th, 1896, two days before admission, she had taken a dose of castor oil and a few hours afterwards was seized with a sudden acute pain in the abdomen and profuse vomiting. At the same time the temperature rose to 101·6° and the abdomen rapidly became distended and tender on pressure. On Dec. 31st the patient's condition remained the same, but the pain and tenderness seemed distinctly worse over the right iliac fossa than over the rest of the abdomen. On admission on the evening of Jan. 1st, 1897, the condition was as follows. The patient was evidently very ill. The temperature was 101°; the pulse was 132, regular, and of fair strength; the respirations were 40. The tongue was covered with a thick white fur, but was moist. Frequent bilious vomiting occurred. There was general distension of the abdomen, accompanied by extreme tenderness and rigidity on palpation. No localised swelling could be felt, and the rigidity and tenderness were not more marked in one part than in another. The bowels were constipated. The liver dulness was not obliterated. No prior history of abdominal trouble was ascertainable. At 9 P.M. on Jan. 1st the abdomen was opened in the middle line below the umbilicus and was found to contain a large quantity of thin, foul-smelling pus which seemed diffused all over the peritoneal cavity. In the right iliac fossa a few recent adhesions were felt. The abdominal cavity was flushed with warm water and drained with a Keith's tube. The patient's improvement was slow but constant, and by Feb. 12th she was walking about the ward apparently well. On Feb. 17th she felt a sudden intense pain in the centre of the abdomen. Her pulse rose to 150, her temperature sank to 97°, and she vomited once. There were moderate general abdominal distension and marked tenderness on pressure just to the left of the umbilicus. This condition gradually passed off and all symptoms had disappeared at the end of ten days. At the present time the patient is perfectly well.

Remarks by Mr. GAMGEE.—In this case the diagnosis of suppurative peritonitis was fairly clear, but the cause was doubtful. However, the condition for the fortnight preceding operation, and more especially the greater intensity of the pain at the onset of the second attack in the right iliac fossa, made it appear probable that the peritonitis was caused by a perforation of the vermiform appendix, and this diagnosis was borne out by the discovery of a few recent adhesions in the right iliac fossa. In treating a case of this nature the question always arises as to whether a prolonged search should be made for the appendix; but the patient is, as a rule, in such a condition as to preclude any prolonged operative procedure, and so simple incision, flushing, and drainage give the best chance of recovery.

WORCESTER GENERAL INFIRMARY.

A CASE OF INGUINAL HERNIA WITH BLADDER IN THE WALL OF THE SAC.

(Under the care of Mr. T. BATES.)

FOR the notes of the case we are indebted to Mr. Robert J. Hillier, who was acting at the time as house surgeon.

A man, aged sixty-four years, suffering from retention of urine, applied at the casualty department of the Worcester General Infirmary on the night of July 30th. A catheter was passed without any difficulty whatever and the bladder was emptied. Nothing abnormal was noted in the urine; but it was observed that he had a small tense inguinal hernia on the right side. Attempts to reduce this failed, and on questioning the patient it was found that he had been constipated for three or four days and had vomited once that day. The hernia, he said, had frequently been down before, but had up to that time never given any trouble in reduction. There was no impulse in it on coughing. He had never worn a truss. He was advised to enter the infirmary at once, but refused to do so. The next morning he again visited the casualty department, having suffered considerable pain from the hernia during the night. There had been no more vomiting and the bowels had acted freely early that morning. The hernia was found to be larger, quite as tense, and still irreducible and without impulse on coughing. He was again advised to enter the infirmary, and this time he consented to do so. He was at once put to bed and an icebag was applied to the hernia. About midday Mr. Hillier made an attempt at reduction, and almost immediately the whole swelling disappeared with the characteristic gurgling feeling and sound. On passing the finger into the ring there still seemed to be some slight thickening which at the time was considered to be a thickened sac. A pad and spica bandage were applied until a truss could be obtained. Late in the afternoon of the same day, a truss having been procured, Mr. Hillier proceeded to put it on the patient, but as soon as the pad was removed the hernia reappeared; and this time it could not be reduced. As it was not then paining him, and as there were no symptoms of strangulation, it was decided to leave him alone until the next day. On the next morning (Aug. 1st) it was found that he had had a good night and had slept well. There had been no vomiting; but his bowels had not acted and the hernia had increased still further in size. He had taken plenty of nourishment, and up to this time had had no trouble with his urine since admission. He was ordered a castor-oil enema, which he returned almost immediately with hardly any fæcal matter. At the same time he passed a little urine, which was blood-stained in appearance, but of which a specimen could not be obtained for more accurate examination. Late in the afternoon a final attempt at reduction was made, but again without result. In the evening Mr. Bates decided to operate. The skin incision was made parallel to Poupart's ligament and as far outwards as the mid-Poupart plane. The sac was opened in the usual manner and was found to be empty. It was ligatured at its neck, cut off, and the stump replaced in the abdomen. As soon as this was done, what appeared to be another and thicker sac was found lying internal to, and partly behind and adherent to, the first one, and having attached to it several large tags of fat. This second supposed sac was also opened, and then almost immediately the fact was recognised that it might be the bladder, and a catheter passed per urethram confirmed the suspicion by appearing in the wound, from which some urine which at first was thought to be peritoneal fluid had escaped on incision. The wound in the bladder having been carefully united by about a dozen Sänger and Lembert sutures of sterilised silk, and some of the above-mentioned tags of fat ligatured and removed, the skin incision was sutured over the unreduced wounded portion of the bladder, a drainage-tube being inserted along

Digitized by Google

the whole length of the incision with its ends protruding at each angle of the wound. The whole was dressed with the double cyanide gauze. The patient stood the operation extremely well, and very quickly recovered from the effects of the anæsthetic (ether). Next morning it was found that he had passed a very good night and had had no pain or sickness; his pulse was very good and he expressed himself as feeling so well that he wanted to get up. He had passed sixteen ounces of urine per urethram without any difficulty whatever. The urine contained blood and urates, but the amount of the former was not at all excessive. From this time onward he made a perfectly uninterrupted recovery, the amount of blood in the urine rapidly decreased, and in a few days disappeared altogether. The wound was dressed on the third day, the tube was removed on the fifth day, stitches were removed on the tenth day, and the bowels acted first on the eighth day after a saline purge. The temperature never rose above the normal, and at no time was there any leakage from the tube or wound which could point to the vesical wound not being perfectly watertight. The small portion of bladder in the ring was not subsequently reduced, but was left where it was found at the time of the operation, and although there is a slight impulse in the scar on coughing this piece of bladder gives him no apparent discomfort. The herniated portion of the bladder belonged to the part below where the peritoneum is reflected from the bladder to the anterior abdominal wall, and consequently had no true peritoneal coat, although it was covered by the peritoneal sac of the intestinal hernia, which sac was adherent to it.

Remarks by Mr. HILLIER.—The chief reason of course for reporting this case (for permission to publish which I am indebted to the courtesy of Mr. Bates) is not so much the treatment (although that was sufficiently instructive) but the rarity of this condition. On looking up the literature of the subject I find that Mr. Macready records thirty-six cases, of which twenty-six were scrotal, four labial, two femoral, one vaginal, one perineal, one ischiatic, and one ventral. Undoubtedly the condition is a very rare one, and since the publication of Mr. Macready's book there do not seem to have been more than about half-a-dozen cases recorded. The cause of the condition seems to be very obscure; most writers upon the subject incline to the view that the bladder is dragged through the ring by a hernia to which it is adherent. Mr. Treves has recorded a case[1] from which he argues that it is due to a growth of pre-vesical fat along the inguinal canal which drags the bladder finally through the ring. In the case under notice both conditions were present—viz., the bladder was adherent to the sac of the original hernia and also some of the pre-vesical fat was outside the ring, so that it was quite impossible to decide with any degree of certainty which was the actual determining cause. It has been stated that if a thick cushion of fat is found at or about the neck of a hernial sac the near proximity of the bladder is to be suspected, and the point seems to me to be one well worth remembering. In nearly all the cases that I have been able to find the patients have been fat persons.

[1] THE LANCET, June 8th, 1895, p. 1424.

PROPOSED SEAMEN'S HOSPITAL FOR CARDIFF.—At a meeting of the executive committee of the Cardiff Seamen's Hospital Fund held on Sept. 27th, under the presidency of the mayor, it was stated that the subscriptions received up to that date amounted to £10,924. This includes the sum of £5000 which was promised by Lord Bute conditionally upon £30,000 being raised.

BRISTOL ROYAL INFIRMARY.—At the half-yearly meeting of the committee of the Bristol Royal Infirmary, held on Sept. 28th, the Rev. S. W. Wayte, who was in the chair, said that the alterations in the operating theatre recommended by the late Mr. James Greig Smith would probably be carried out during the next few months. Soon after Mr. Greig Smith's death some of his friends, acting independently of the infirmary authorities, formed a committee having Mr. Arrowsmith as chairman and Mr. F. B. Girdlestone as treasurer, with the object of setting up a bust in the museum and library and a medallion in the infirmary as memorials of him. Subscriptions were still being asked for with a view to the fund being closed. The subscriptions to the infirmary had unfortunately fallen off considerably, and the treasurer was authorised to sell £2000 of the invested capital.

Reviews and Notices of Books.

Doctor Mendini's Hygienic Guide to Rome. Translated from the Italian and Edited, with an Additional Chapter on Rome as a Health Resort, by JOHN J. EYRE, M.R.C.P., L.R.C.S. Irel., D.P.H. Camb. London: The Scientific Press. 1897.

"ROME would be one of the healthiest of cities if it were not Rome"—if it were not, that is to say, a city of catacombs, of basilicas and churches, of picture galleries and sculpture galleries, of ruins and excavations, all of which attract the visitor, generally with limited time at his disposal and so tempted to over-exert body and mind in his eagerness to miss nothing during his sojourn.

The sentence which we have quoted is written by Dr. Gsell-Fels, a physician by profession and a man of letters as well, whose guide-books to Italy, from "the Alps to Etna," have won the admiration of authorities like the late Professor Freeman for their fulness, trustworthiness, and critical discrimination. It conveys a just opinion, as statistics more than demonstrate, and it sounds a note of warning which the world of travel is extremely prone to neglect. The "foreign resident" in Rome who "does as the Romans do" has never reason to complain of the city's unhealthiness. Indeed, he is generally able to "make more of life" than in any other European capital, and certainly, as English-speaking residents can testify, he often reaches a longevity rarely equalled elsewhere. But it is quite another affair with the "foreign visitor" whose stay is restricted to weeks or even days, and who generally contrives to pack into his brief holiday an amount of sight-seeing—that is, of physical and mental fatigue—which makes him a "candidate" for whatever insanitary mischief may for the moment be prevalent either in the air, the water, the soil, or the conditions inseparable from concentrated population. In ninety-nine cases out of a hundred, as generations of English-speaking or, for that matter, of French or German practitioners can attest, it is the "foreign visitor" with his imprudences and his ignorance or defiance of local experience and prescription who incurs disease or premature death in Rome, and whose "record" has wrought for the city that evil name which at no time, assuredly not since 1870, has it deserved.

It is to this class—an annually increasing one—that Dr. Mendini addresses the carefully compiled "Hygienic Guide" so opportunely given to the English-speaking world by Mr. J. J. Eyre. "Carefully compiled," we say; for few or none of his observations are original or are other than familiar to readers of the professional journals in London, Paris, Berlin, or Vienna. But Dr. Mendini is an accomplished physician and a trained observer, and in his work of compilation he generally knows by personal experience and independent research what to select and what to omit from the publications of his predecessors. Very full and satisfactory is the section on the Mortality in Rome and other Italian Cities, from which it appears that, measured by her national sisters, Rome has much the smallest death-rate in general and is much less subject than they are to special diseases such as small-pox, scarlet fever and measles, diphtheria, typhoid fever, or tuberculosis. In illustration of this follows another section on the Physical Robustness of the Citizens founded on the examination of the young men who yearly present themselves at the conscription to be passed into military service. Of the rejections Rome gives fewest—19·68 per cent. of those examined; while Turin in "robust upper Italy," as it has been called, heads the list with 21·99.

The section on the Relative Salubrity of the Several

Digitized by Google

Quarters of Rome introduces us to a full and carefully illustrated chapter on the Climate, in which we find tables on temperature, humidity, cloud, rain, and wind which tell their own tale, and that, in comparison with other health resorts even in Italy, an eminently reassuring one. The section on Malaria which follows is (thanks to the translator) brought up to date by a succinct statement of Dr. Manson's "Mosquito Theory" supplemented by Surgeon-Major Ross's experiments in relation to it; but the prescriptions of How to Protect Oneself from Malaria are far from complete—witness the omission of Dr. Tommasi Crudeli's lemon potion (more than once described in THE LANCET), by which that eminent physician and hygienist protected a vast number of labourers employed in constructing a railway through a notoriously malarious tract of southern Italy. A word of caution too should not have been left out as to the use of quinine without medical advice. The reckless consumption of "that veritable poison to the vaso-motor system," as Dr. Tommasi-Crudeli calls it, explains on the part of many a patient in Rome his non-response to the drug when properly prescribed by the physician, to say nothing of the fact that it is often unprofessionally taken in cognac or whisky as a vehicle, so as seriously to compromise the hepatic and renal viscera at a time when their functional power should be at its best.

The Waters of Rome form the subject of a very useful chapter, mainly drawn from the analysis made by the Senator Professor Cannizzaro and Professors Nasini and Piccini in 1884, of which a full account was given in THE LANCET[1] towards the close of that year. But we need not follow Dr. Mendini chapter by chapter throughout his serviceable and opportune manual, nor need we do more than pass a cordially favourable judgment on Mr. Eyre's supplement on Rome as a Health Resort, addressed primarily to his own countrymen. Rather let us point out a few blemishes which ought to disappear before the volume finally takes its place on the bookshelf of the busy consultant or in the knapsack of the academic visitor. Mr. A. B. Stevens, M.A., M.B. Oxon., who is responsible for its revision in proof, should have been careful to weed out the numerous errors in classical quotation which disfigure it—for instance, the sentence from Herodotus (p. 15), which neither the Father of History nor any Greek, it is safe to say, ever wrote; or the citation of Sextus Gullius (*sic*) Frontinus (p. 39); or the reference to "Vitige," which all English scholars spell "Vitiges" (p. 50). Even the English style savours too much of the amateur in its rendering of the Italian—for example (p. 8), "may be *retained as being* absolutely correct" would be more idiomatically rendered "may be *held to be*," &c. Such blemishes are surprising, to say the least, and ought certainly to be removed in the next edition, even though they do not materially impair the value of a volume at once useful and well-timed.

Handbook to the Workmen's Compensation Act, 1897. By M. ROBERTS JONES. Cardiff: Tudor Printing Works. 1897. Price 1*s*.

THIS is a *brochure* of some seventy-eight pages containing the text of the new Workmen's Compensation Act and some comments on it such as a perusal of the statute suggests. It is no doubt intended to be the forerunner of a law-book upon the subject, and the commentary for the most part is subjoined to the text in the form of what is in effect a subsequent chapter. This is not a very convenient mode, from the reader's point of view, of arranging the materials of a work of reference. In this case, however, in which the authorities are largely, if not indeed mainly, derived from the debates in Parliament occasioned by the passing of the Bill there is a fitness in the collection in this way of the comments in a separate chapter which can be bodily removed from the book in a subsequent edition without serious mutilation of the part which will be left remaining. This no doubt will happen when the impromptu utterances of statesmen can be replaced by the more authoritative deliverances of the Courts.

The legislative experiment which this Act will set on foot is one of great range and interest, destined probably to have momentous consequences in the future. The trades immediately affected are railways, factories, mines, quarries, and engineering works. Indirectly affected, as being certain to share eventually in the benefits of the scheme, or of some modification of the scheme, if it should be found to work out to the advantage of the community, are practically all industrial undertakings throughout the length and breadth of the land. Its results will therefore be canvassed with the greatest eagerness as soon as there are any results to be reported. Till then it is perhaps premature to dogmatise as to whether the security afforded to the workman of compensation in any ordinary case of injury from accident will tend to occasion carelessness, and so to diminish the security of life and limb, or whether the new responsibility cast upon the employer will stimulate his interest in the safety of his workmen to such an extent as to increase the security of industrial employment. Anything like intentional self-injury is no doubt sufficiently guarded against by the clause which provides that the statutable compensation shall be disallowed in any case in which the injury is attributable to the serious and wilful misconduct of the workman injured.

Among the provisions introduced for the benefit of employers is a very proper regulation that the workman who makes a claim must submit to medical examination by a practitioner appointed by the employer and acting in the employer's interest. Medical men are to be appointed for the purpose of the Act by the Home Secretary, to whom the arbitrator or judge when adjudicating upon a disputed claim may refer for a report upon the injury occasioned by the accident.

LIBRARY TABLE.

The Origin of Matter and Force. By R. C. SHETTLE, M.D. St. And., Consulting Physician to the Royal Berks Hospital, Reading. London: Simpkin, Marshall, Hamilton, Kent, and Co. 1897. Pp. 56.—In this pamphlet an attempt is made to establish a scientific theory of the mutual relations of matter and force in the production of all physical and vital phenomena, and to show from a physical point of view that the *works* of God testify absolutely to the truth of the *word* of God. An immense amount of original thought is shown throughout every page. Dr. Shettle is a conscientious observer. We do not intend to enter fully into his arguments in this review, but we wish to point out to the author the wrong impression he makes when he uses the terms "inspired author" and "the first chapter of the book." Anybody who takes up this pamphlet and reads the first few pages will imagine that Dr. Shettle is about to justify the creation of the world in six periods of twenty-four hours; but as the reader advances he finds that such is not at all the writer's intentions; the period required for the creation of the world is not mentioned—the first two *verses* of the Bible only are taken and discussed with relation to accepted physical laws. We have read the arguments with considerable interest, but we have not space to set down the lines of thought along which he travels; we can, however, recommend the perusal of the treatise to all who are interested in the vital questions therein considered. Two of the paragraphs given in the summary which concludes

[1] THE LANCET, Dec. 20th, 1884, p. 1125.

Digitized by Google

the pamphlet may be quoted as showing the general idea of the work. "I have now attempted to show—(1) that the universe was created and is maintained in its present state by means of power which, when originally impressed, produced various degrees of density, and so brought every form of matter and gravity into existence. ..... (15) That the human soul is an entity, the germ of which was given by the Creator when man became a living soul, ... that the inner man is typical of the outer man; is the seat of memory; and records within itself the life-history of the individual, just upon the same principle as is embodied in the formation of the seed germ in vegetable life."

Traité de Gynécologie Clinique et Opératoire. Par S. POZZI, Professeur Agrégé à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Broca, Membre de l'Académie de Médecine. Troisième édition. Avec 628 figures dans le texte. Paris: Masson et Cie. 1897.—This, the third, edition of Professor Pozzi's valuable work on Gynæcology maintains the high standard of excellence of those which preceded it. The work has been carefully revised, and several chapters have been completely altered. Especially is this so as regards the sections of the book dealing with asepsis, with the surgical treatment of fibromyomata, with the indications for vaginal hysterectomy in pelvic suppuration, and with the procedures suggested for the treatment of backward displacements of the uterus. There is an excellent account of Pelvic Hæmatocele and Extra-uterine Pregnancy. The author's opinion on the relation of these two things accords with that held generally here by the best authorities—namely, that pelvic hæmatocele in the immense majority of cases is "only a chapter in the history of extra-uterine pregnancy." Professor Pozzi's book ranks as one of the best standard works on the subject of which it treats. The references are both copious and cosmopolitan.

The Student's Guide to Medical Diagnosis. By SAMUEL FENWICK, M.D. St. And. and Durh., F.R.C.P. Lond., Consulting Physician to the London Hospital, and W. SOLTAU FENWICK, M.D., B.S. Lond., M.R.C.P. Lond., Physician to the London Temperance Hospital, Physician to Out-patients at the Evelina Hospital for Sick Children. Eighth edition. London: J. & A. Churchill. 1897. Price 9*s.*—Fenwick's Medical Diagnosis is so well known and has proved useful to so many generations of students, that it is unnecessary to do more on this occasion than call attention to the fact that this the eighth edition has been brought thoroughly up to date as regards the latest discoveries in the science of which it treats. Perhaps the statement that actinomycosis almost always ends fatally is a little too sweeping, for several instances of recovery, though not of course where the lungs or liver were affected, have been recorded under the use of large doses of iodide. This, however, is a slight blemish upon an excellent work. The descriptions are admirably clear, and the all-important subject of pathology is rightly put in the forefront. Any student who works carefully with this book in the out-patient room and at the bedside should have no difficulty, even if he cannot satisfy himself as to what a disease actually is, in being able to say pretty certainly what it is not.

La Technique des Rayons X. (The Production and Practical Employment of the X Rays.) Par ALEXANDRE HÉBERT, Préparateur à la Faculté de Médecine. Paris: Georges Carré et C. Naud. 1897. Pp. iv. and 134. Price 5 francs.—The practical applications of the x rays as described by M. Hébert are to all intents and purposes exclusively medical and surgical. Having introduced the subject with a few paragraphs on the recognition of foreign bodies, whether embedded in the tissues or impacted in the œsophagus, larynx, &c., he next deals with the observation of the process of repair occurring in bones from which sequestra have been removed, and in fractures which have been united by metallic fastenings (wiring, screws, &c.). Several instances are given in which the rays have been of service in the diagnosis of the diseases of bone, the most recent being a case communicated to the Academy of Sciences by M. Potain, who was able to distinguish chronic osseous rheumatism from gout by the fact that the increased density in the former condition, due to osteitis, caused the extremities of the bones to appear darker than usual on the fluorescent screen, whilst in the gouty patient the ends of the phalanges and metacarpal bones presented pale markings showing a diminution of the normal opacity. The examples of diagnosis of thoracic disease include three cases of inflammation of the right pleura with effusion, under the care of Dr. Bouchard; in the picture on the screen the affected side was darker than the other one as far as the upper border of the effusion, the shadow increasing in depth towards the base of the lung until the liver was reached; as the fluid became absorbed the transparency of the lung returned. In phthisical patients the transparency of the tuberculous portions of the lungs was found to be diminished. In addition to the various medical and surgical applications of the rays, some of which have just been enumerated, M. Hébert suggests that they may be of service in the detection of unauthorised articles sent through the post-office, and that they may assist jewellers in distinguishing between real and imitation diamonds. The sections describing the various forms of Roentgen ray apparatus and their use, as well as the chapter on photography, are very complete and are copiously illustrated with engravings. There are also ten full-page or folding plates with photo-prints of Roentgen photographs of hands, human fœtuses, small animals, &c.

The Return to Nature. By JOHN FRANK NEWTON. *The Life of William Lambe, M.D., F.R.C.P Lond.* By E. HARE, C.S.I., Inspector-General of Hospitals. London: The Ideal Publishing Union. 1897. Pp. 158.—Of these two monographs, originally published at distant intervals, and now bound together in one volume, the second is the most interesting. Dr. Lambe, who was a graduate of Cambridge University, went from Warwick to London in the year 1800, and soon attained a somewhat prominent position in the Royal College of Physicians of London, being Censor for several years, Croonian Lecturer in 1814, 1815, and 1816, Harveian Orator in 1818, and Consiliarius in 1839. He was born in 1765, and having suffered much from ill-health while a young man he renounced animal food in 1805, and from that time till his death in 1847 he was a strict vegetarian. Moreover, he drank only distilled water, regarding which he wrote in 1819 that distillation properly conducted is really a less troublesome process than filtration. Mr. Newton, who wrote the "Return to Nature" about 1811, was a friend of Dr. Lambe, and, like him, a vegetarian. He lays considerable stress on the good health and good looks of the family which he had brought up on this system, and mentions with satisfaction that only sixpence was charged for medicine in his apothecary's bill for a household of seven persons in the year 1810.

JOURNALS AND REVIEWS.

The Monist.—In a paper on Egg-structure and the Heredity of Instincts Professor Jacques Loeb, of the University of Chicago, endeavours to show that the complicated mechanism of the instincts is the result of very simple circumstances which do not require any complicated structure for their transmission through the egg. For instance, the caterpillars of Porthesia (a butterfly) are oriented by light—i.e., the light causes them to bring their plane of symmetry into the direction of the rays of light

Digitized by Google

and to turn their oral pole toward the source of light. "This process is purely mechanical. The light produces in the skin of the animal a change (probably chemical), and this produces, through the central nervous system, changes in the tension of certain muscles. ..... This is also the mechanism by which the moth is forced into the flame. There is no such thing as an attraction of the moth by the light, but its fatal flight is only due to an orientation." Chemical substances emanating from putrefying meat or cheese have the effect of orienting the female of the common fly, the result being that the eggs are deposited on these materials by a reflex action without any assistance from either experience or conscious choice. Professor Loeb also offers an explanation of the continuity of bodily form in successive generations irrespectively of qualities transmitted by the egg.

Journal of the College of Science, Imperial University, Japan. Vol. X., Part 2.—The present number is entirely zoological and botanical, the titles of the six articles being as follows: A Species of Ephelota occurring in Misaki and its Spore Formation, by Professor C. Ishikawa; Iron Bacteria in the Warm Springs of Ikao, and Sulphur Bacteria in the Warm Springs of Yumoto, by Professor Manabu Miyoshi; the Development of the Gonophores in Physalia Maxima, by Professor Seitaro Goto; the Development of the Pollen Grains in Allium Fistulosum, by Professor C. Ishikawa; and the Formation of the Heart in Petromyzon, by S. Hatta. Abstracts of the papers on Iron Bacteria and Sulphur Bacteria have already appeared in THE LANCET, the former on Sept. 4th, p. 611, and the latter on Sept. 25th, p. 805. The first five articles are in German and the concluding one is in English. There are seven full-page plates of illustrations. The publishers are Maruya and Co., in Tokio, and R. Friedländer und Sohn, in Berlin.

FROM
THE LANCET LABORATORY.

TABLOIDS OF ERYTHROL TETRANITRATE.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL-BUILDINGS, E.C.)

THE therapeutic action of the organic nitrates and nitrites, as is well known, has been very closely studied during recent years, with the result that some very valuable vaso-dilators have been added to the materia medica. The latest addition is represented in erythrol tetranitrate, which is now supplied in the obviously convenient form of tabloids. It is said to be valuable in conditions of cardiac pain with high arterial tension, and recently it has been employed with excellent results as a vaso-dilator in angina pectoris, and in the asthmatic attacks of chronic nephritis. In angina pectoris it appears to have been used not with the idea of replacing amyl nitrite and trinitrin in stopping an attack after it has manifested itself, but in preventing its onset.

(1) COCOA ESSENCE; (2) SOLUBLE COCOA.

(THE TOWER TEA, LIMITED, 5, JEWRY-STREET, E.C.)

The soluble cocoa (which is a cheap article) is admittedly a mixture, being mixed with arrowroot. "Tower Cocoa Essence" is a very pure cocoa which has had an exceptionally large proportion of the indigestible fat removed. It was found to contain only 19·5 per cent. fat, the lowest amount we have ever recorded. From a consideration of the amount of ash and its degree of alkalinity it is evident that the cocoa has not been treated with alkali. The ash amounted to 1·8 per cent., and its alkalinity to 0 51 per cent. reckoned as potash. The cocoa is not held in suspension in the infusion as long as desirable, and in a short time there is a considerable sediment at the bottom. There are now well-known processes in vogue by which this may be avoided and the cocoa made, as is dietetically desirable, more miscible.

DIGESTENZYMES (DAMANCY) IN TABLETS AND PILLS.

(AGENCY: ARTHUR AND CO., 69, BERNERS-STREET, OXFORD-STREET, W.)

Chocolate is the excipient in these tablets, which contain diastase, pepsin, pancreatin, and bismuth, together with phosphates and albuminoids. We have proved the digestive activity of the tablet on starch as well as on white of egg in both an alkaline and acid medium. The activity of the enzymes present is thus established. The tablets should therefore supply a distinct aid along the whole alimentary tract in providing the specific enzyme that may be indicated. It is stated that the enzymes are combined in such a way as not to have any prejudicial action on each other during the exposure of the food to the various digestive processes.

DIASTOL.

(THE STANDARD MALT EXTRACT COMPANY, LIMITED, 21, WATER-STREET, LIVERPOOL, AND 23, BILLITER-STREET, E.C.)

Diastol is a comparatively thin, clear, limpid, reddish-brown liquid containing a very large proportion of the active digestive principle of malt. It contains a distinct amount of alcohol and possesses a strong, rich, malty taste. In our experiments we found that on adding a few drops of diastol to thick starch paste the mixture became brilliantly clear in a few seconds, and in as many minutes the solution was perfectly free from starch, complete conversion into maltose having resulted. The advantage of such a preparation in amylaceous dyspepsia is obvious, since all the digestive properties of diastase are presented unassociated with an excess of sugar as is the case in ordinary malt extracts. The dosage is thus very materially reduced, while its digestive activity upon starch may be relied upon.

EAU MAICHE.

(THE INDUSTRIAL INVENTIONS DEVELOPMENT COMPANY, LIMITED, BROOK HOUSE, WALBROOK, E.C.)

Eau Maiche is described as "bi-oxydised (*sic*) water," and is, in fact, nothing more than peroxide of hydrogen of such a strength that, as our analysis shows, one volume contains nearly three volumes of available or loosely-combined oxygen. Hydrogen peroxide is no new introduction as a cleansing and deodorising agent in the treatment of foul wounds and suppurating surfaces. The sample before us contained a distinct amount of chloride. Eau Maiche, however, is also recommended to be taken internally, but the claims made in respect of its curative effects are such as we are in no wise prepared to endorse. As one example of this we may quote the following: "There have been many cases of cancer where not only has growth been entirely arrested, *but, as far as can be judged in the time*, all traces have been removed from the system." The italics are ours.

ELECT EXTRACT OF COCOA.

(ROWNTREE AND CO., COCOA WORKS, YORK.)

Our examination of this cocoa showed that, in the first place, a cocoa of excellent quality is selected; and, secondly, that it is carefully prepared so as to develop its nourishing qualities and to make it to a high degree miscible with hot water. These desirable characteristics have been attained by that peculiar mode of preparation based on the Dutch process which adds to the mineral constituents of the cocoa without necessarily making it alkaline. We found that the cocoa contained 32 per cent. cocoa fat and 7·84 per cent. mineral matters. The alkalinity of the incinerated cocoa was equivalent to 2·88 per cent. The cocoa gives a good, rich infusion of exceptional strength and of fine flavour, and is found to be free from objectionable sediment, even after standing for some time.

New Inventions.

A "WRIST-EASEL"

(With tracing tablets specially adapted for facilitating the drawing of the appearances found in cases of disease of the throat, nose, or ear).

THE "Easel" is a plate of thin metal measuring 3 inches in height by 2¼ inches in width. It is fixed on to the "wrist-clip," a somewhat omega-shaped strip of metal, which can be readily clipped on to the left arm and as readily removed. The easel plate is attached to this by means of a flattened loop of metal which slips on to a hook. In order that the plate may be in the most favourable position for drawing while the left hand manipulates the laryngeal mirror or the nasal or aural speculum this hook is placed obliquely on the "wrist clip." The drawing card is held firmly in position on the easel by means of spring catches or of a frame hinged to its top and fixed down over it. The illustration will convey the disposition of parts. The "tracing tablets" consist of layers of tracing paper, under the uppermost of which is placed a card bearing the conventional outline of the normal appearance of the part under examination—membrana tympani, larynx, &c. The observer can rapidly sketch over this the abnormal appearance even if not endowed with skill in draughtsmanship, and the rest of the outline can be traced out at the same time or later either by himself or by an assistant. The "outline cards" used by the deviser of the instrument represent the normal larynx during phonation and inspiration (on one card), the fauces, the post-rhinal image, the anterior nares, the transverse vertical section of the nasal cavities, the membrana tympani of each ear with (on the same card) the inner wall of each tympanum.

The ordinary indiarubber-stamped outlines may of course be used on pieces of paper of suitable size fitted into the "wrist-easel," but the "tracing-tablets" present the great advantage that the sketches made, while traced as far as possible on the given outlines, are not confused by the retention of these along with the new ones.

Messrs. Mayer and Meltzer, of Great Portland-street, W., have constructed the apparatus most satisfactorily.

DUNDAS GRANT, M.A., M.D., F.R.C.S. Eng.

PEAT WOOL (BÉRAUDINE).

IT is now many years since peat was first introduced as a surgical dressing, but the results were not perfectly satisfactory. It certainly absorbed the discharges well and kept them sweet, but the peat was very friable, and in great part it was in the form of a powder, and as it had little tendency to cohere it was necessary to enclose it in gauze bags. These objections detracted greatly from its value in surgical cases and it could not be called an elegant dressing. We have had the opportunity of examining the Béraudine Peat Wool, and may say at once that it possesses all the advantages and none of the disadvantages of the unmodified peat. All the dusty portion of the peat has been removed, and only the fibres of the mosses, of which the peat in great part consists, have been retained. The resulting product is a brownish mass composed of innumerable interlaced fibres; it is completely free from the powder, which is so great a hindrance to the employment of ordinary peat, and it forms a very soft dressing. Its absorbent power is great; we found that one specimen took up more than twelve times its own weight of water, and after it is fully saturated it has not nearly so much tendency to cake together to form a hard mass as cotton wool has. Its elasticity, too, is great, and therefore it is of value in cases where it is desired to exert an elastic compressing force. It is further claimed for it that it has antiseptic properties; without going quite so far as this we may say that it seems to possess the power of retarding the growth of micro-organisms, and this, of course, enhances its value. Altogether we consider it to be a useful dressing, especially in cases where great power of absorption of discharges is required. We are not aware of the cost of this peat wool, but if not more expensive than cotton wool it should largely replace that substance in surgical practice. It is manufactured by the Peat Industries Syndicate, Limited, 15, Walbrook, London, E.C.

FOCIMETER AND LENS ANALYSER.

THIS instrument has been devised by Mr. W. Banks, of Astley Bridge, Bolton, for the purpose of ascertaining the focal length of lenses and for indicating whether they are spherical, cylindrical, prismatic, or combinations of these. It is an instrument of precision founded on the principle of placing the lens, the power of which it is desired to ascertain, in the path of rays rendered parallel by a convex lens. If the spectacle lens to be examined be convex the parallel rays issuing from the lens attached to the focimeter are brought to a focus on a slip of paper which can be moved along a rod supplied with a scale or index and its strength easily read off. When the spectacle lens to be examined is a strong one the slip of paper will have to be brought nearer to, and when weaker to be removed farther from, the source of light. In the event, however, of the spectacle lens being concave the parallel rays issuing from the focimeter lens are rendered divergent and consequently do not unite on a focal point. In this case a second lens is introduced into the focimeter which is termed the analysing lens. This lens is of known, and rather high, power. As the position of the principal focus of this second lens is known, it is obvious that the focus will be removed to a greater distance from the lens after the rays have been rendered divergent by their transmission through the concave spectacle lens. The difference between the first and second foci gives the power of the concave lens. The analysis of a sphero-cylindrical lens is accomplished by placing it on the stage in the same manner as a spherical lens and the screen is moved along, commencing near the focimeter lens, until an approximate focus is obtained. The disk on which the lamp is mounted is then revolved until the image of the incandescent filament coincides with the axis of the cylinder, when the scale indicates the focal length of the combination and the line of light on the screen will coincide with one of the angular divisions into which the latter is divided and give the inclination of the axis of the cylinder. On turning the lamp at right angles to its former position the refractive power of the spherical lens alone will be indicated at some distance along the graduated scale. The first reading minus the second gives the strength of the cylinder. The deviation caused by prisms is also shown on the screen, which is marked in metre angles. Mr. Banks claims for the instrument that determinations of the power of all kinds of lenses can be made with rapidity and exactness. The few trials which we have made lead us to believe that it is a reliable instrument. The price, with three sets of analysers, special electric lamp, dry battery, and switch, is £3 17*s.* 6*d.*

THE LANCET.

LONDON: SATURDAY, OCTOBER 9, 1897.

THE medical session has been duly opened, and the introductory lecture still shows every sign of vitality. There are some schools, indeed, which affect a superiority to such things. At Guy's Hospital, for example, the opening ceremonies are little advertised and are said to be of a strictly domestic character. Students and their teachers and friends, however, gather together very much as in other schools, and are favoured with two addresses instead of one. On this occasion Sir SAMUEL WILKS, who presided, was greeted with unbounded applause evoked by the honours conferred on him by his Sovereign and by his College. Not only did he preside, but he delivered himself of many quaint and characteristic thoughts on the present state of the profession and of medical science, which will be remembered many years by the students to whom he spoke. In addition, he was succeeded by Dr. MUSPRATT, of Bournemouth, a loyal alumnus of the school, who delivered an address on several subjects of great practical interest to students, giving them some conception of the duties which they are being trained to meet and of the spirit in which those duties ought to be discharged.

Introductory lectures must not be regarded merely from the student's point of view, though to him, unless he be a very superior or a very conceited person, they cannot fail to be of use. They are of obvious interest to the public, as is shown by the space and the attention given to them by the leading organs of the press. The medical profession is essentially the silent profession, and its wisdom has to be expressed for the most part in the consulting-room of practitioners or in the houses of patients. But a very cursory study of society and of contemporary literature and civilisation is enough to show that this silence of the profession may be overdone. The profession has advice to give to the public, it has warnings to utter, it has claims to advance, it has complaints to make, and grievances to ventilate. For all these purposes there are few suitable opportunities, and one of the few is the introductory lecture at the opening of the medical schools. It is pleasant, too, to the profession to see the duty of the introductory address put occasionally into the hands of laymen. This course was happily followed in the present session at St. Thomas's Hospital, where Principal FAIRBAIRN discoursed on medicine as only a divine and a scholar of his learning and character could have spoken. It is so customary for members of the profession to hear from those outside it words of criticism or censure that it is gratifying that so capable a critic as Principal FAIRBAIRN should express the opinion that it is wonderful for medicine to have been able to achieve so much as it has done. At the Middlesex Hospital Lord STRATHCONA AND MOUNT ROYAL gave an interesting address on the medical schools of Canada and the devices of those who in the remote north-west regions of the Dominion have to meet their diseases without medical aid. He does not advise English medical men to go there without personal connexions or some predilection, as the medical schools of Canada, eleven in all educate a number of men practically sufficient to supply its wants.

One pleasant feature of the opening addresses of the medical schools is the wide range of subjects discussed. Occasionally this leads the orator to make a slightly excessive demand on the time of his audience, not to say their patience. But it would be difficult to say that any of the subjects were irrelevant or unfit for the care and consideration of medical men and it is no slight testimony to the interest infused into the subjects that such lectures—exceeding the length of ordinary lectures—should be so well listened to. Sir JAMES CRICHTON-BROWNE excelled himself in the eloquence with which he vindicated some old-fashioned doctrines of mind and conscience while showing his familiarity with all that is latest in the achievements of physical research. His protest against the realism and coarseness of much of our current literature and the disposition to exalt the natural above the moral in man is much needed, and it is to be hoped will be taken to heart by writers. He speaks with a large knowledge and experience of man both in health and disease, and he magnifies free will and the individuality of man as distinguished from the most anthropoid of his fellow creatures. If few of us can play the part of great men that "exceed their antecedents," and have no explanation in their environment, we can all "build up the being that we are" and in a smaller sphere magnify our free will with no other compulsions than those of duty and of virtue. It will be well for every student to read Sir JAMES CRICHTON-BROWNE'S address in its entirety and to yield to the spirit of its teaching—"hold fast to the importance of the individual and do not worry yourselves about the insignificance and evanescence of man." The address of Dr. WILLIAM CARTER, of Liverpool, at Charing-cross Hospital will also well repay perusal with its fine appreciation of "the everlasting expansiveness of medicine," of the victories over disease which it has already achieved, and greater ones yet in store. By way of emphasising the indispensable importance of independent and close personal observation of disease and the exercise of a manly and independent judgment he quoted the case of LAENNEC as that of one whose great work was founded mainly on cases accurately observed in his student days. While Dr. CARTER and other speakers recognised the inevitable tendency to specialism and division of work, they were careful to deprecate all narrowness and to insist on the necessity of broad general knowledge of disease as the only adequate basis for the erection of special knowledge and practice. It is simply pitiable to see a narrow specialist spending his own strength and his patient's perhaps scanty means in investigating a prominent symptom of a patient's case and leaving unnoticed the wider taint of the blood or constitution of which the local evil, for which he is sought, is a mere limited and secondary expression. Dr. CARTER was justified in insisting on the enormous influence of medical opinion on society. The questions on which medical opinion is desired, as

Digitized by Google

Mr. RAYMOND JOHNSON pointed out, are ever extending with the growing range of medicine itself, and tend more and more to share with philosophy, and even divinity, the regulation of man's life in all its stages. The medical man must adapt the teaching that he has to give to all classes of men. It may be true, as Dr. CARTER says, that our effect will depend entirely on the respect which we can gain for our opinions among the thinking portion of mankind who constitute its true rulers, but grievous mischief creeps in—witness the position of the vaccination question—if we cannot also influence the imperfectly educated classes who are now in a very real sense our rulers. Dr. PATRICK MANSON reminded us of the extent of our empire by pointing out to us that many of our students will be called on to treat diseases of climates and countries other than our own, and urged the importance of including instruction in such diseases as a part of the regular curriculum. This ought to be done by the Medical Schools and Examining Boards apart from the influence of the General Medical Council. But it is so urgent that the General Medical Council will not always be justified in withholding a strong expression of its opinion. Mr. RAYMOND JOHNSON did well to impress on his hearers the importance of individual practical work in the fundamental subjects of anatomy and physiology and to remind them that examinations are not the final test of a man's worth. Is it not a condemnation of much in our present examinations that they are not more practical in their nature, that they do not more faithfully tell a man's character and capacity, and forecast the result of the great examination that awaits all students after qualification—their ability to cope with actual disease in actual patients, or, as he well puts it, with "the disease and the person"? Dr. PYE-SMITH at Sheffield, Mr. D'ARCY POWER at the Royal Veterinary College, and Mr. J. GROSVENOR MACKINLAY at the Royal Free Hospital, illustrated other aspects of medical study which we have not space to discuss. Students may be somewhat alarmed at the range of knowledge covered by these addresses and the amount of study they imply. Let them note also that the best teachers enjoin rest and recreation as well as work. Ours should be a cheerful profession. We study disease with a view to its mitigation and removal—even its prevention. Let students learn to avert it by lives in accordance with the laws of health and with the high philosophy that is enforced in the able addresses which it has been our pleasure to publish.

THE rapid development and widespread prevalence of typhoid fever at Maidstone clearly indicate that we are in the presence of an epidemic spread by water. Other causes may produce epidemics, but none are so effective in the rapid propagation of the disease as a contaminated water-supply. How fatal such a contamination may be has been proved only too often. Already 4 per cent. of the population at Maidstone have contracted the disease, and this reckoning is based on the population of the entire town. The number of inhabitants of the central district, which was not supplied with the contaminated water and which consequently escaped, is not known, otherwise it could be shown that, in the parts of the town where the infected Farleigh water was drunk, the percentage of cases is much higher. Yet results far worse than this have followed on the contamination of a water-supply. For instance—and to give an extreme case—in 1887 an epidemic of typhoid fever due to water contamination broke out at the Collège de Cluny in the department of Saône-et-Loire, France. There were 215 pupils in this school, and no less than 119 suffered from the fever. This is not 4 per cent. of the population, as at Maidstone; it is more than 50 per cent. But this brings us face to face with an all-important difference in predisposition which has not yet been sufficiently noticed, discussed, and examined at Maidstone. It is obvious that the pupils living in a large school are all submitted to the same predisposing influences. Whatever defects there may be in the drainage, the ventilation, the food, and the condition of the subsoil of the school, the pupils collectively experience these unwholesome influences. The same cannot be said of the inhabitants of a town. There is a far greater variation of conditions; and, consequently, though the contaminated water may be equally distributed to each, the effects it produces are very different. Therefore, though it is in the first instance essential to ascertain what is the distributive medium or cause of an epidemic, this in itself in no wise suffices for the thorough elucidation of the problem. It is first necessary to discover what is the distributive medium, because the most practical measure that can be taken during the emergency is to lay hands on that medium and destroy it. But it would be worse than folly to imagine that, having done this much, no further measures need be adopted. If we treat a patient we have to deal, not only with the acute stage of the disease, but above all true medicinal treatment depends on the successful treatment of those constitutional conditions which rendered the disease possible. A town, like a patient, is composed of individual molecules which together conglomerate to form a collective whole. Some parts of the body are strong and wholesome; others are weak and susceptible to disease. The object of sanitary science is to discover and remove the cause of this difference. If no such difference exists at Maidstone why is there not the same proportion of cases of fever at Maidstone as at the Cluny school? Surely it is in the existence of these differences that we shall find most valuable indications as to the true means of preventing or limiting future epidemics.

Guided by these principles, our Special Commissioner, who proceeded to make investigations on the spot, first fully described the water-supply, as this was undoubtedly the medium by which the epidemic was spread. This week, however, we publish an account of what may be qualified as the predisposing causes. These are more complex, but they are also very suggestive. First with regard to the different levels in the town. On either side of the two rivers, the Medway and the Len, there is a zone of considerable size where the ground is low-lying and does not in any place exceed an altitude of 40 ft. It is precisely on this low-lying ground that there has been no fever. Then, if we take the next zone, which varies from 40 ft. to 100 ft. in altitude, we find here also a general immunity from the fever. The exception is in the south-eastern district; but even here the epidemic appears as if it only began at an altitude of 78 ft. The map which we publish likewise indicates the fever-stricken districts, which are for the

Digitized by Google

most part above 100 ft. in altitude. These last correspond exactly with the districts where the contaminated Farleigh water-supply was distributed, but it will be seen that they also correspond with the high levels. The suggestion is then made that the sewer air has easier access to the dwellings on these high levels. The branch sewers run down steep gradients to collecting mains below, which are badly constructed, having insufficient fall. The branch sewers may therefore act as ventilating shafts for the main sewers which pass below and which generate a great volume of sewer gases because they are not self-cleansing. On the other hand, sufficient details are given to show that the house drains are far from perfect. Sewer air will naturally be attracted by the heat within dwellings and thus reach the inhabitants unless the house drains are very carefully trapped and ventilated. From all these facts, we are justified in surmising that the inhabitants of those streets and houses where the greatest number of cases of fever has occurred (and these streets are also marked in the map), have been breathing a larger volume of sewer air than their more fortunate neighbours. In the lower districts where the branch sewers do not descend such sharp gradients they are less likely to act as ventilation shafts; and though these lower districts were not supplied with the contaminated water, their inhabitants must, to some extent at least, have occasionally drunk the contaminated water when they visited friends in what subsequently became the infected areas. Yet these inhabitants of the central district have, practically speaking, escaped the epidemic. It would seem as if they were living under conditions rendering them less susceptible to the typhoid contagion.

Then there is also the question of the subsoil that may help to account for this marked difference in respect to predisposition. Mr. MATTHEW A. ADAMS, medical officer of health of Maidstone, has already shown, in a remarkable paper communicated to the International Congress of Hygiene, held at Budapest in 1894, how the prevalence of diphtheria in Maidstone followed upon the rising of the water levels in the subsoil. He is now engaged in making similar comparisons with regard to the present epidemic of typhoid fever, and we may here again find another predisposing cause. We have already before us this fact, that a certain portion of the soil in the non-infected district is of clay and therefore less porous than the soil in the infected districts. Also, it has been found that some of the sewers in the infected district were in a very defective condition and likely to contaminate the surrounding subsoil. Consequently, it would be most imprudent to rest satisfied with condemning only the water-supply. If immunity from typhoid fever depended only on a pure water-supply and not on any other consideration, then—if we may judge from the precedent afforded by the experience acquired at the Cluny College mentioned above—there should be at Maidstone, not 1400 to 1500 cases of typhoid fever, but something more like 15,000 cases. Most fortunately, the inhabitants of Maidstone are not all equally predisposed as were the pupils of the college in question; but does not the enormous difference in the percentage of cases at Maidstone and at the Cluny College clearly indicate the immense importance of studying, and then of removing, all predisposing influences? That such influences still exist at Maidstone our Special Commissioner has attempted to demonstrate; and in so doing will, we believe, have rendered no slight service to the cause of sanitation.

THE votes of the registered medical practitioners of England and Wales must all be recorded by to-morrow (Saturday), and doubtless the great majority of voting papers have been returned. It is to little purpose to enlarge further on the questions at stake or the fitness of the rival candidates. It is satisfactory that the contest has been practically narrowed to one of two candidates. As the profession grows in experience of its elective duties and in detecting the qualities which go to make a really effective and desirable representative it is reasonable to hope that candidates will become fewer in number and sometimes will agree with the number of the vacancies to be filled. The opponents of Direct Representation feel fortified when they see anything like the arts of electioneering practised in the selection of a member of the General Medical Council. This is a strong reason why the friends of Direct Representation should avoid the appearance of such arts. It would be pitiable indeed if it should prove advantageous to a candidate to have recourse to methods for influencing registered medical men similar to those which are considered fair and even necessary in political warfare. Sir WALTER FOSTER cannot be charged with having instigated the notice of himself in the *Young Man* with a view to his candidature for the vacant seat on the General Medical Council. This for two reasons—it must have been well in hand, we imagine, before he could have been aware of the mysterious movements in Dr. RENTOUL'S mind, and, secondly, he must have been cognisant that such a notice was not likely to commend itself to medical men or to help his election. But we are sorry to find him making a defence of the notice even as a political method. Such notices are accorded by many journals of which better things might be expected to members of the profession, and presumably they have some value or they would not be desired. But that a politician of Sir WALTER FOSTER'S calibre, and an eminent member of the medical profession, should justify such a notice is unsatisfactory. He cannot complain at being asked to explain his responsibility for it, and while we readily acquit him of any reference to the election to the General Medical Council in sanctioning it we are still sorry that he should in any way assist in the diffusion of such literature.

The result of the election will not be officially declared until Saturday, the 16th inst. As far as the programmes of the rival candidates go the difference between them is very slight. Our reasons for preferring Mr. VICTOR HORSLEY on this occasion are that he was first in the field, that he has a quite exceptional knowledge of the defects of the Medical Acts, and that he feels a remarkable sympathy with the rank and file of the medical profession. Both candidates are members of the British Medical Association. Sir WALTER FOSTER is the older member and has very strong claims—claims of past services and claims of present

Digitized by Google

ability. But these were not pressed last year when the pressing of them would have involved no opposition to one of the most brilliant and, we will add, one of the most active members of the Association, so that we may be allowed to express our feeling that the prominence given to them now is a little inopportune. The result will soon be known. Whichever of the two candidates is elected the cause of Direct Representation will not suffer, and we may expect the Council to go on its way without those explosive incidents which are injurious to its reputation as the controlling body of the medical profession and as an intermediary between that profession and the State.

Annotations.

"Ne quid nimis."

THE NEW GOVERNMENT LABORATORIES.

THE English nation is supposed to move slowly in regard to the application of science to industrial processes, and of late we have heard a good deal of the necessity for educating men in special scientific work with the view of applying their knowledge to the manufactures and arts. Germany we know is a long way ahead in this respect, but in the completion of the new buildings last week close by King's College Hospital, which contain admirably equipped laboratories for carrying on the duties of an important department of revenue work, this country has taken an initiative. For not the least interesting feature about the new building is that it is the first State laboratory in this or any other country which has been specially designed for the departmental work which was formerly carried out in a few incommodious rooms in Somerset House. The work of the Somerset House chemists has increased enormously during the last decade. Originally—and it is now more than fifty years ago—the principal work done for the Government was that of detecting the adulteration in tobacco. This soon extended to the examination of beer. The laboratory then consisted of a few rooms situated in Arundel-street, Strand. So rapidly did the field for Government analysis widen that special rooms were provided in Somerset House in the year 1859. And here the services of the chemists proved to be in request by almost all the Government departments. Thus to them were referred the stores, provisions, and other supplies for the troops, and perhaps the India Office put forward more claims to the skill of the department than any other section of the Government. Later, when in 1875 the Food and Drugs Act came into operation, the onus of reference was thrown upon the staff at Somerset House who thenceforward came to be regarded as officially the Government analysts and referees. All this has involved, as might be imagined, a large increase in the working staff and a need for better accommodation suited to the increasing requirements. In 1867 the laboratory accommodation at Somerset House consisted of at the most three rooms, but later twenty rooms were occupied for the purpose. In 1867 again the number of samples analysed was 9055, and in 1887 39,224, and last year no less than 64,664 samples were analysed. These figures appealed to the Treasury Office when they were brought to their notice, with the result that it was agreed to provide a separate establishment for the work, and Dr. Thorpe, who was appointed the Principal of the Government laboratories a year or so ago in succession to Dr. Bell, undertook to draw up the plans of the new laboratories and to supervise their construction. All this has been done, and the laboratories are practically complete and occupied by a staff numbering over seventy. It need hardly be added, in view of Dr. Thorpe's great practical knowledge of the construction of the leading laboratories abroad, that the new Government laboratories are equipped with appliances and apparatus that are fully in compliance with modern requirements. The sum voted by the Treasury towards the completion of the work was nearly £30,000. Our own interest in the new Government laboratories is centred of course in the administration of the Food and Drugs Act, in the disputed cases coming under which the chemists at the new laboratories are the referees. The public analysts have from time to time entered many complaints of the reticence of the Government chemists as to the methods they employ and have taken very strong exception to the apparently low standard of food, and especially of milk, which they have adopted in reference cases. We confidently expect that these objections will be met when the new Bill comes into operation. It cannot be doubted that the work of reference is entrusted to skilled men, and it is only as to the interpretation based upon the results of analysis that the differences of opinion have occurred. But we believe that the standards thus adopted by the referees were not below those capable of justification under the present law. In the proposed new Bill a court of reference is suggested which should be empowered to deal with the subject of prescribing limits and standards of the quality and purity of food as well as with other matters such as the use of antiseptics. In whatever way the administration of the Acts may be modified in regard to referred samples it is evident that the new laboratories and the increased accommodation will considerably facilitate the work of this department and add to its usefulness in the interests of the general community.

THE HEALTH OFFICER OF THE CALCUTTA CORPORATION.

SANITARY science has conferred many benefits on the community, but a cordial public recognition of the fact is so uncommon an event that an instance of it deserves special notice. It happens now and then that medical or surgical services rendered to individual patients may be substantially rewarded, but the care of the public health seems not to appeal either to sentiment or to the popular imagination; its results are not always immediately apparent, and from the nature of the case it is inevitable that some departments of medical practice must dwindle in proportion as preventive medicine advances. The union of sanitation and preventive medicine has had the effect of prolonging the average duration of human life, of raising the general standard of health, and of controlling epidemics so that they are now but little more than semblances of what they used to be in the pre-scientific era. To the readers of THE LANCET these are mere commonplaces, but the public at large bestow only vague and casual attention on such subjects unless their interests are touched by the inconveniences of quarantine in foreign countries or by the heavy outlay entailed by modern drainage systems or by the demolition of insanitary buildings. Under these circumstances it is gratifying to find that at Calcutta the work of Dr. W. J. R. Simpson, the health officer of the corporation, is so highly appreciated that on the occasion of his retiring from his appointment an influential public meeting was held for the purpose of presenting him with a farewell address. The ceremony took place in the Dalhousie Institute on Sept. 4th, and among the numerous company were the Honourable Mr. Justice Rampini, Mr. W. R. Bright, chairman of the corporation, Colonel Wilford, Mr. E. N. Baker, collector of Calcutta, Mr. W. Parsons, secretary of the Bengal chamber of commerce, and Mr. L. P. D. Broughton, Administrator-General of Bengal; many members of the corporation were also present, both British and natives being represented. Mr. Bright

presided, and opened the proceedings with an eulogistic speech in the course of which he said that for the past eleven years Dr. Simpson had brought all his energies to bear on the task of improving the sanitation of the town, and now that he was compelled by ill-health to leave Calcutta he would in his retirement carry with him the good wishes of all who knew him. Dr. Bolai Chunder Sen, president of the Calcutta Medical Society, then read the farewell address, which has been published in the Calcutta *Englishman*, and contains the following passage: "The period of your incumbency as health officer of this city has been signalised by many important sanitary measures, the credit of which is largely due to your undaunted zeal and unwearied perseverance. Among the more important of these have been the inauguration of measures to prevent pollution of the subsoil and to place on a sounder basis the drainage system of the town; the introduction of the principle of incineration of the town refuse; the demonstration of the need of efficient building regulations for the town; the organisation of an agency for the investigation of the causes and course of preventable diseases and the adoption of preventive measures; the establishment of a well-appointed laboratory, the first of its kind in India, for food analysis and bacteriological research; the reorganisation of the departments of food inspection and registration of births and deaths; the testing of the results of Professor Haffkine's system of anti-cholera inoculation and the timely precautions taken to prevent the importation of plague into Calcutta. The medical public is under deep obligation to you for re-affirming the relationship between small-pox and cow-pox; for creating an epoch in the history of medical progress in India by largely assisting to bring to a successful issue the first Indian Medical Congress; for urging the necessity for the whole of India of an organised sanitary service which the Government of India has fully endorsed. Your successful researches into the bacteriology of rinderpest, your contributions to the etiology of tropical diseases, and the able manner in which you have acquitted yourself as president of the Calcutta Microscopical Society, as secretary to the Calcutta Medical Society, and as editor of the *Indian Medical Gazette*, will be long and gratefully remembered by your colleagues in the medical profession in this country. In bidding you farewell and God-speed we wish you and Mrs. Simpson a safe and pleasant voyage home and long life with health and happiness." Mr. Hughes, chief engineer of the corporation, then made some complimentary remarks, after which Dr. Simpson spoke at considerable length, saying that the occasion was one to which his wife and himself would look back with pride and that this kindly acknowledgment of his work was particularly gratifying and refreshing after the labour of eleven years, which had been spent in placing the health interests of Calcutta on a sound basis. He concluded as follows: "I wish to thank the members of my own profession for the appreciation which they have expressed of my work in connexion with the Indian Medical Congress and the proposals therein made and afterwards approved of by the Government of India for the organisation of a sanitary service in India. I trust that it will not be long before the proposals of the Medical Congress are put into practice, to the advantage of the Indian medical profession and of the country at large. In leaving Calcutta I am specially sorry to take leave of the officers of my own department who have worked with me so long. There is Dr. Sen, the able assistant health officer, who has been with me for nearly ten years; there is Dr. Ram Mitter, the deputy superintendent of vaccination, whose services in the cause of vaccination in Calcutta are invaluable; there are also Dr. Dutt and Dr. Ghose, both expert analytical chemists, Dr. Mittra, Dr. Mookerjee, Dr. Lahiri, and Dr. Chatterjee, excellent food inspectors, Dr. Chowdry, an expert at anti-cholera inoculation, Dr. Dass and Dr. Roy, excellent medical inspectors able to find out by inquiry, if any one can, the causes which have led to an outbreak of disease. In departing from Calcutta I have the satisfaction of knowing that I leave behind me a small band of Indian medical men, the first of their kind, who are sanitary experts and who are thoroughly trained in the principles and practice of public health." Mr. R. D. Mehta, in proposing a vote of thanks to the chair, observed that it was to a large extent through Dr. Simpson's efforts that the plague had been prevented from reaching Calcutta. The proceedings then terminated. Before going to India in 1886 Dr. Simpson had acquired a large experience in the diversified questions connected with public health administration. For five years he was medical officer of health and police surgeon to the city of Aberdeen; he was also lecturer on public health in Aberdeen University and president of the Sanitary Association of Scotland. In 1883 he was in Egypt observing the epidemic of cholera, and he drew up a report on the subject which was presented to Parliament in 1884; in the same year he was appointed to hold a special inquiry on behalf of the Local Government Board into the prevalence of diphtheria in Somersetshire and Wiltshire.

ERGOT BEFORE DELIVERY.

A CASE was recently reported in the Manchester papers in which a midwife was stated to have given a dose of ergot in a case of complicated presentation where she ought at once to have sent for a medical man. Mr. Broadbent was ultimately sent for. He found it to be a presentation of footling, funis, hand, and vertex. The midwife seems to have examined the case at 9.45 P.M., and then, instead of sending for medical assistance, she appears to have failed to recognise the complexity of the case, and administered a dose of ergot. Mr. Broadbent, who saw the patient only at 11.30 P.M., found the presentation as above stated; the cord was pulseless, and all the parts presenting were jammed, so that he was not able to deliver till 2.30 A.M. An inquest was held on the child, at which the midwife said in reply to the coroner that when she gave the ergot she was not aware of the serious nature of the case. The practice of giving ergot before delivery merely to expedite labour is undoubtedly bad. In all well-managed maternity departments midwives and students are forbidden to give ergot till after the placenta has been expelled. The tonic contraction of the uterus produced by ergot is fatal to the child by interfering with the utero-placental circulation if for any reason delivery does not take place rapidly after the ergot has been administered; and there is, as regards the mother, a very appreciable risk of rupture of the uterus, if there is any obstacle to the expulsion of the fœtus.

THE VALUE OF CLINICAL OBSERVATION TO THE STUDENT.

OWING to the multiplicity of subjects to which the unfortunate medical student is now required to devote himself for the purpose of examination there is no small danger that he will be led to forget the practical part of his profession, and two of the addresses delivered at the opening of the medical year laid special stress upon this matter from different points of view. At St. Mary's Hospital Dr. W. J. Gow referred to the importance to the student of familiarising himself with medical and surgical technique and quoted a remark of Lord Armstrong to the effect that a man's success in life depended far more on his capacity for useful action than upon his acquirements in knowledge. Intelligent clinical study, too, said Dr. Gow was of the utmost importance. At Leeds Mr. T. R. Jessop recounted his experience at Moscow and related how surprised he was to find what a magnificent

Digitized by Google

hospital that ancient city possessed. Standing about two miles outside the city it consisted of some dozen blocks, every one devoted to some special branch of medicine or surgery.[1] This building had been erected by the munificence of private individuals, supplemented by a Government and municipal grant. Here, then, was the centre for teaching the future medical men of Russia, and Mr. Jessop naturally expressed a hope that a similar institution might arise in England. The nearest approach to the Moscow ideal is afforded by the hospitals of the Metropolitan Asylums Board, but even they are not Government institutions though they are municipal in a way, and means for familiarising the student with the clinical details of the infectious fevers are still very far from complete. As to a State grant for hospitals the only instance we can call to mind of the State dealing with a hospital is not encouraging, for it is the case of the robbery of the revenues of St. Bartholomew's by Henry VIII. In time, however, the State may recognise that it is as important to train up medical men as to teach board school children "social economy."

CONGENITAL FACIAL PARALYSIS.

AT a recent meeting of the Society for Neuropathology and Psychiatry in Moscow Dr. Minor showed a case of this character presenting some interesting features. The patient was twenty-six years old. He was born of an intemperate mother, but no instruments were used at his birth. He was, however, much asphyxiated, being of a dark blue colour all over. At the moment of birth it was observed that the face was strongly drawn to the left side. This condition still persisted and in an aggravated form, but psychical development had gone on naturally until he was eighteen years of age, when he began to suffer from epileptic attacks. When he was shown there was facial paralysis on the right side. The zygomaticus major had escaped and so had the upper part of the orbicularis oris. The platysma was much atrophied and no electrical response to either current could be obtained in the muscles other than those mentioned as having partially or wholly escaped. Dr. Minor regarded the condition as the result probably of an intrapontine lesion, perhaps a hæmorrhage in the facial nucleus occurring at the time of birth and associated with the asphyxia which was present. Some speakers, however, thought that the lesion might be in the nerve. Similar cases, it is pointed out, have been described by Schultze and Bernhardt, and also by Möbius. The last-named has described them as cases of nuclear disappearance in infancy.

ANOTHER RAILWAY FATALITY.

DEATH has once more come to a passenger while travelling by train without any accident having happened to the train itself. On the arrival of the Manchester express at Liverpool on the night of Sept. 30th the window of a first-class carriage was found to be broken and the carriage and footboard were bespattered with blood and hair. On the line being searched between Manchester and Liverpool the body of a man much mutilated was found on the line close to Brunswick Dock Station at the south end of Liverpool. The body was lying near some empty coaches which were standing in a siding and the window in one of them was broken. At the inquest held upon Oct. 2nd it was stated by the foreman shunter who searched the line that the side lamp on the stationary train, which was unlighted, was much bent. The carriages were standing in a tunnel and close to them he found the body of a man. The right leg was cut off and the head was much injured. It was not the custom to light the lamps of a stationary train. It seems evident that the unfortunate man, who has been identified as Mr. H. S. Harvey, must have been looking out of the window—or rather leaning out of it—have come into violent contact with the broken lamp, and so have been dragged out of the window, and cut up by the train in which he had up to that moment been travelling. There are cases on record of travellers having been killed by striking their heads against something when looking out of a carriage window but we do not remember any instance of a passenger being dragged out of the carriage. It is always easy to be wise after the event, but it cannot be too strongly impressed upon the mind of the travelling public that to lean out of a carriage window is highly dangerous at all times, and doubly so when passing through a tunnel or in the dark. The jury added a recommendation that stationary trains on the central line should in future be lighted, but probably if this had been the case in the present instance it would have made no difference. The serious part of the matter seems to us to be the statement of the foreman shunter that there was only a space of twenty inches between the projecting part of the empty train and any train passing it. To widen the tunnel would be, we suppose, a matter of some difficulty, but surely a siding might be constructed for the reception of empty trains in some other part of the line where more space could be afforded.

MEDICAL EVIDENCE AT CORONERS' INQUESTS.

AN inquest recently held at Twerton, near Bath, disclosed some interesting medico-legal points. Shortly, the case was as follows. A man, aged forty-seven years, reached his home about half-past eleven at night and almost immediately went out to the stable. About ten minutes afterwards his wife called to her son that she heard her husband groaning. The son found his father lying on the footway near the stable, and on being questioned he replied: "Someone knocked me down." The son raised him up, and he managed to walk two yards, but could go no further, and he never spoke again. The son added that the father's trouser pockets were turned inside out, and a £5 note which deceased was supposed to have had in his pocket was not there. In contradiction to this Dr. Heathcote, who was the first medical man to see the deceased, said that on arriving he found him lying dead on the footway; he wore trousers with a flap, and the right-hand pocket was lying outside the flap, but not turned inside out. Deceased had a wound on the back of the head and a slight cut over the right eye. At a post-mortem examination he found a lacerated wound over the left elbow and a bruise over the right eye. The heart was enlarged and fatty, the liver fatty, and the spleen and kidneys were engorged with blood and enlarged. In his opinion death was due to cardiac failure, the wounds on the head and elbow were caused by the fall, and the bruises on the face by the deceased having struggled in the road or having fallen against the wall. He thought that the deceased fell in the middle of the road, got up, walked to the foot-path, fell again, and then got up and fell or leaned against the wall, on which there were marks of blood. People dying under such conditions often had erroneous impressions as to the cause of their falling and were apt to attribute the pain they felt in the head to a blow. The solicitor representing the deceased's family put a series of questions to Dr. Heathcote suggesting that a person dying from cardiac failure could not get up after having fallen. Could Dr. Heathcote cite any similar case from a medical book as to this point and his evidence as to erroneous statements being made under similar circumstances? To this Dr. Heathcote replied that he was giving his own statements,

[1] Illustrations of the Moscow Clinique and of some of its various departments will be found in our Special Supplement, "Medicine, Past and Present, in Russia," published on Aug. 7th.

Digitized by Google

and the coroner refused to allow the solicitor to pursue this line further without notice. The solicitor called another practitioner (Dr. W. H. Cooke), who said that he considered that a person dying from sudden cardiac failure would not get up after having fallen down. In the end the jury returned a verdict of death from disease of the heart, but whether accelerated by shock of any kind there was no evidence to show. We think everyone will agree that the coroner deserves the thanks of the profession for the way in which he conducted this inquiry. Here were two medical men giving evidence on the same questions and taking an apparently opposite view, but, as the coroner said in summing up the case, Dr. Cooke had not attended the post-mortem examination, but simply gave his evidence on generalities. As to the verdict, he said, they might return one absolutely in accordance with the evidence of Dr. Heathcote. This the jury proceeded to do and we think everyone will agree with it.

SMALL-POX IN CYPRUS.

ACCORDING to a communication from Reuter's agent at Larnaca, published in the *Times* of the 2nd inst., an epidemic of small-pox broke out towards the end of last month in Cyprus and was especially severe in the Turkish quarter of Larnaca, other parts of the town having been likewise attacked. The appearance of the disease in Larnaca was soon followed by an exodus of people from that place to other towns and villages in the island, and it is feared that the disease disseminated in this way may soon become widespread unless prompt and stringent precautions are taken. The disease is stated to have been introduced by a Turkish family from Béirût. Very inadequate means for the isolation of the sick, and those of the most primitive kind, exist in Cyprus as may well be imagined; there is a paucity also of medical attendance; and we know next to nothing of the condition of the population of Cyprus as regards vaccination. It seems probable that the island will furnish another object lesson of what the ravages of small-pox may effect among an unprotected population. There are some advantages in living under British rule under such circumstances as these, for we do possess laws for the repression of contagious disease and the machinery for practically applying them.

VARICELLA GANGRÆNOSA.

OUR knowledge of varicella gangrænosa is still so incomplete that every well-recorded case is of interest. In the September number of the *Archives of Pediatrics* are given two good examples of the disease. The first is described by Dr. William F. Lockwood, of Baltimore, and is accompanied by a photograph. A well-nourished female child, aged two years, exhibited the eruption of varicella. Next day a wide zone of dusky red dermatitis occupied nearly the whole surface of the trunk. Rapid ulceration of the spots within this area ensued. The contents of many of the vesicles became hæmorrhagic. Bleeding from the mouth and nose occurred and blood was extravasated in the skin over the pubes and about the genitals. The gangrenous spots varied in depth, and in size from a pea to a surface measuring 1 in. by 2 in. They often occurred where there were no varicella vesicles. On the trunk were large patches where the epidermis only was removed, exposing purplish dry surfaces. These were due to the dermatitis, and did not radiate from the chicken-pox vesicles. The deeper spots showed a dry, hard, black eschar in the centre, an ulcerating border, and an elevated inflamed edge. The left eye was closed from swelling and ulceration of the upper lid, and there was free purulent discharge from between the lids. The child emitted an extremely fetid odour. Death took place on the eighth day, apparently from broncho-pneumonia; but satisfactory examination of the chest was not possible. The second case, described by Dr. Lewis Mann Silver, of New York, was that of a boy in good condition, aged two years. The illness began with diarrhœa, which was followed by a temperature of 103° F., lethargy, and a convulsion. On the fourth day the body was covered with the characteristic rash of varicella. The mucous membranes of the mouth and conjunctiva were congested. On the third day of the eruption circles of congestion from ¼ in. to ½ in. in width were noticed around several of the spots, which had become black and depressed in the centre. Next day three gangrenous areas, measuring from 1 in. to 2½ in. across, appeared on the neck. On the following day both eyelids were so much swollen that they could not be opened, and there was a profuse discharge of blood and serum from the mouth and nose. The urine contained abundant albumin and numerous granular casts. The child died in the evening soon after a convulsion. It is curious that varicella, the mildest of all the infectious diseases, should present such a grave complication. What explanation can be offered? Mr. Hutchinson, who first described the disease, attributed the occurrence of the gangrene to idiosyncrasy, as it usually occurred in healthy children. Dr. Barlow, however, denies this and asserts that in none of his cases were the children healthy. A second infection by some microbe supervening on the varicella has also been offered as an explanation, but evidence on this point is wanting.

EXACT LOCALISATION AND MEASUREMENT BY THE X RAYS.

AS most workers with the Roentgen rays know it is often very difficult to ascertain by the photographs they produce the exact locality of foreign bodies embedded in the tissues. The x ray photograph fails to give any definite information as to the exact position and size of the foreign body, and the surgeon when exploring for it has met with disappointment and dissatisfaction because he may have caused his patient pain without discovering the *locale* of the foreign body. This has detracted very considerably from the value of x rays in surgical work. A method, therefore, which ensures the exact localising of the foreign body in both a vertical and a horizontal plane and the exact determination of its size will be of immense service. We hope shortly to bring to the notice of our readers an account of this method which has been carefully elaborated by Dr. W. S. Hedley and Mr. Mackenzie Davidson. For the present all we need say is that the method of measurement employed renders the x rays a really accurate means of locating the position and size of foreign bodies in the tissues. At a demonstration at which we were present the results were satisfactory and convincing both as to the practicability and utility of the method, while it relieves the patient of any unnecessary inconvenience and detention.

SURGICAL SYMPTOMS IN CONNEXION WITH FILARIA SANGUINIS.

AT a recent meeting of the Bombay Medical and Physical Society Surgeon-Lieutenant-Colonel W. K. Hatch called attention to the enlargement of various lymphatic glands and the varicose state of the lymphatics of the spermatic cord which are met with in cases of filaria sanguinis. A full description of the former of these conditions has hardly, he said, been given by any writers with the exception of Dr. Patrick Manson and the late Dr. Vandyke Carter. The gland usually affected are those in the groin, and next in order of frequency the axillary, then the iliac glands, and very rarely those of the neck. The glands have usually a soft, doughy feel and when small can be made almost to disappear, but when the pressure is removed they gradually resume their

Digitized by Google

former size. These glands are subject to periodical enlargement, becoming tense, hot, elastic, and often extremely painful; the patient at the same time suffers severely from fever, lasting for several days, during which he is quite incapacitated for work. The filaria sanguinis can generally be detected in the blood at night during the attacks, hence the difficulty of diagnosis (which may be considerable) arises from making an examination in the interval between the attacks. The glands have an open spongy structure with numerous large lymphatics in connexion with them on all sides; if they are opened while still in the body a large quantity of reddish fluid escapes. Such enlarged glands have been sometimes mistakenly attributed to femoral hernia, to pelvic inflammation, &c. They should generally be left alone; if they are removed the healing of the wound is usually tedious. In one case in which Surgeon-Lieutenant-Colonel Hatch was prevailed on to operate against his inclination all went well for a few days, but suddenly the temperature went up, the face became dusky and the extremities livid, the circulation in the radial arteries and then in the brachial ceased gradually, and the patient sank. A case of varicose lymphatics of the spermatic cord has been operated on in the Jamsetjee Jejeebhoy Hospital. This patient had no enlargement of the testicle, but in other cases both cords and both testicles were large, smooth, and elastic, and moderate hydrocele was present.

COFFINS ONE PENNY ONLY.

THE heart of the Funeral Reform Association must be glad, for never in its most exalted moments could it have imagined that a coffin would be supplied at the price of one penny; and yet we learn that the Contracts Committee of the Preston Union have accepted a tender for the supply of coffins at prices ranging from one penny to fourpence each. The coffins are to be of specified good quality. According to the *Yorkshire Post* the explanation of this bargain is that "in some instances the friends of deceased persons have club money to draw which enables them to purchase a superior class of coffin, the contractor thus recouping himself for the penny articles." We do not quite see the logic of this argument, but the fact remains that a coffin may be purchased for a penny. The sums wasted upon funerals—and by none more than by the very poor—are a perfect scandal, although we know that the expense is incurred out of a mistaken idea of showing reverence for the dead. This is a feeling all too rare nowadays and should be respected, but it would be much better to turn it into a more useful channel. If half the sums now squandered on horses, plumes, mutes, and other pagan vanities were handed over to the ecclesiastical authorities of the parish to be spent in relieving the poor and destitute, with a provision that the name of the deceased should be commemorated, reverence for the dead would be kept up, their memory would be kept green, and some, if only a small portion, of unhappiness would be relieved. The Preston guardians will, we hope, now that a coffin can be purchased for a penny, make the funeral of a pauper somewhat less of a perfunctory ceremony than it is at present and take some care to show that a body should not be huddled into the ground at the cheapest rate and in the most careless manner. Extravagance, as we have said above, is to be avoided, but decency and dignity should by all means be considered.

A MEDICAL VICE-CHANCELLOR AT CAMBRIDGE.

WITH the appointment of Dr. Alexander Hill as Vice-Chancellor of Cambridge University the medical profession has for the first time in history the satisfaction of seeing the highest executive office in one of the two great English universities filled by a medical man. John Caius, who, like Dr. Hill, was a student of St. Bartholomew's Hospital, ruled over the College, which he re-founded and endowed, from 1559 to 1573, but he did not fill the office of Vice-Chancellor. John Harvey was appointed Warden of Merton College, Oxford, in 1644, but lost his office six months later on the fall of Charles I. Of other medical men, if any, who have filled headships of colleges there is, we believe, no record, Dr. Alexander Hill's mastership of Downing alone excepted. Of late years medicine has made great advances at the universities, and we must look upon the election of Dr. Hill not only to the mastership of Downing but to the Vice-Chancellorship of the University as a proof of the increasing influence of our profession at Cambridge, and also as one of many recent indications that medicine is rapidly stepping into a position of equality with the sister professions of theology and law. Dr. Hill holds the office of Lecturer in Advanced Anatomy to the University. He was for some time Hunterian Professor of the Royal College of Surgeons of England. He is the author of many papers on the anatomy and physiology of the nervous system, the translator of Obersteiner's "Central Nervous Organs," and the author of the "Physiologist's Note-book" and other works. Last year he succeeded Sir William Broadbent as President of the Neurological Society, and it is as a neurologist that he is chiefly known to the profession. With the public his name is also familiar as the chairman of the National Home Reading Union, over which excellent institution he has presided since its foundation eight years ago. Recently Dr. and Mrs. Hill took their children for a voyage round the world, and we understand that the incidents of their travels as well as various observations upon the ethnology, natural history, geography, and the resources of the Queen's dominions will be published during this month by Messrs. Swan Sonnenschein and Co., under the title of "A Run Round the Empire; being the log of two young people who circumnavigated the globe, written out by their father."

WATER ANALYSIS AND TYPHOID FEVER.

THE value of both a chemical and bacteriological analysis of water with a view to pronouncing it fit or unfit for drinking purposes has often been impugned, and this fact has not a little to do with the refusal of some authorities to have the water-supply frequently and systematically examined. This may or may not have been the case at Maidstone, where, unfortunately, one of the severest epidemics of typhoid fever on record has broken out not very long after it was decided to reduce the number of analyses which had hitherto been made. We do not for a moment affirm that had the analyses been made more often the outbreak would have been avoided. Still, the periodic and frequent examination of a water-supply is, in our opinion, a step that should never be neglected, for although neither bacteriology nor chemistry can be depended upon to determine with certainty whether a water is actually injurious to health, yet both alike may afford an indication of risk and impurity. We could quote several instances where a water-supply has been traced with certainty as the source of typhoid fever, yet on chemical analysis the water showed a high standard of purity. And bacteriological examination is just as likely to be misleading as a chemical examination. Indeed, as a rule, where bacteriological examination succeeds in tracing impurity, so also does chemical analysis. The only safe and satisfactory way to control the purity of a water-supply is to have periodic bacteriological and chemical examinations made, and, above all, especially if the results are negative, to make from time to time a thorough investigation of the source of supply and to ascertain every conceivable possibility of contamination, whether occasional or enduring. It must not be forgotten that accidental pollution may

Digitized by Google

happen which would be sufficient to produce an epidemic of disease, and that the moment of pollution may occur sometime between the taking of the samples. In short, it is imperative that not only should a water-supply be examined frequently, both chemically and bacteriologically, but that every step should be taken, especially where the supply is dependent upon wells, to examine minutely the source of the water and ascertain whether there is any possibility of its contamination.

POST-MORTEM EXAMINATIONS AND HOSPITAL PATIENTS.

AT an inquest held upon Oct. 5th at the Lambeth coroner's court a question of great interest to hospital authorities was raised. The inquiry, held at the request of the father of the deceased, was upon the body of a boy aged sixteen years. Five years previously the boy had had his thorax opened and drained at the Westminster Hospital, presumably for an empyema, and the opening had never healed up. On Sept. 18th, 1897, the father brought him to St. Thomas's Hospital, where the boy was admitted. According to the father's evidence, he saw Dr. H. P. Hawkins and told him that he objected to any operation; the boy also objected, whereupon Dr. Hawkins said: "Then nothing shall be done to you, my boy." Witness than left for Brussels, and while there on Sept. 29th he received a telegram saying that the boy was dead. On arriving at the hospital he found that an operation had been performed and a post-mortem examination made. He had given his consent to neither. Dr. H. P. Hawkins, assistant physician to the hospital, said he first saw the boy, who was very ill, having a collection of matter in the right side of his chest, on Sept. 20th. He afterwards saw the father and explained to him that an operation enlarging the opening already present in the side would be necessary. At first the father objected, but upon matters being explained he gave his consent. Dr. Hawkins contradicted the father's statement that he had said "Then nothing shall be done to your boy." Dr. H. G. Turney said that the post-mortem examination was made in the ordinary routine way, and Mr. Sidney Phillips, the steward, said that an order was issued automatically on the occurrence of every death for a post-mortem examination to be made. Consent was never asked, but the friends of a patient were informed as soon as possible on the occurrence of a death, and he considered it tolerably well known that a post-mortem examination would be made. Mr. W. H. Battle said that the operation was performed by him on Sept. 23rd, and the boy died on the 29th from tuberculosis. The jury found that the boy had died from heart failure following tuberculosis, that the hospital authorities were quite justified in operating, and that the father had given his consent. They thought, however, that relatives and friends should be allowed an opportunity of objecting to a post-mortem examination. We quite agree with the verdict; and with regard to the rider, as a matter of fact, we believe consent is asked at most of the metropolitan hospitals. It is very rarely refused if the matter is stated plainly and temperately to the relatives, but the feeling against these examinations is in most cases the outcome of ignorance and, although easily set aside, should be respected and allowed for.

WE are informed that on Sept. 15th, in a case at the Evelina Hospital for Sick Children, Mr. A. H. Tubby successfully and immediately reduced the deformity arising from caries of the spine, and that on Wednesday, Sept. 29th, the same surgeon operated on a similar case with success. These are the first occasions in which this method of forcible reduction has been carried out in London, although Mr. Robert Jones and Mr. Tubby have previously employed it in Liverpool.

THREE courses of lectures and clinical demonstrations will be given at the National Hospital for the Paralysed and Epileptic in each year. During the present or winter course a clinical lecture or demonstration will be given weekly in the theatre on Tuesdays, at 3.30 P.M., by one of the members of the staff. There will be demonstrations on other days as occasion offers. All communications respecting clinical appointments, lectures, and hospital practice should be made by letter only, addressed to the secretary-director at the hospital.

AT the Hospital for Diseases of the Nervous System three courses of clinical demonstrations will be given in the session 1897–98 for medical practitioners and senior students. The courses are designed to cover the subject of neurology in a systematic manner. The first course will commence on Tuesday, Oct. 12th, at 4.30 P.M., and will be continued on consecutive Tuesdays at that hour until Dec. 14th. The fee for one course will be a guinea, and a composition fee of two guineas may be paid for the three courses. Cards of admission may be obtained from the honorary secretary, 60, Upper Berkeley-street, W.

SOME members of the Royal Commission on Tuberculosis, including Sir Herbert Maxwell, Bart., M.P. (chairman), Sir Richard Thorne Thorne, Mr. Cooke-Trench, and Mr. John Speir, have started on a visit to Glasgow, Edinburgh, and Belfast, to see the methods of dealing in the public slaughter-houses at the different places with animals or carcases affected with tuberculosis, and to obtain information on other points connected with their inquiry. On Monday next they hope to visit Dublin for a similar purpose, and possibly one or two English towns on their return.

MR. HUTCHINSON will resume the clinical conferences at the Museum, 211, Great Portland-street, which have been suspended during the vacation, on Wednesday next at 4 P.M. They will be continued every week at the same hour, and the attendance of all members of the profession (not ladies) is invited.

IT is stated by the *Times* correspondent that the Quebec College of Physicians and Surgeons has issued a decree prohibiting medical men from accepting positions as physicians of charitable or benefit societies under pain of withdrawal of the privilege to practise.

AT the opening meeting of the winter session of the North-West London Clinical Society, to be held at the North-West London Hospital on Oct. 20th at 8 30 P.M., the President, Sir William Broadbent, Bart., M.D. Lond., will deliver the annual address.

NO reliable details can yet be given as to the numbers of the new students at the various schools, but we hear that as a whole the total is below the average, although certain schools are rejoicing over a probable increase.

DR. SYDNEY STEPHENSON'S report on the prevalence of ophthalmia in the metropolitan poor-law schools was issued on Oct. 2nd. We shall take an early opportunity of referring to it in detail.

UNIVERSITY OF CAMBRIDGE.—The new Vice-Chancellor, Alex. Hill, M.D. Cantab., Master of Downing College, was formally admitted to office on Oct. 1st. The retiring Vice-Chancellor in a valedictory address announced a gift of £2000 for the general purposes of the university. He hoped that this first response to the statement of needs recently issued by the Chancellor would be followed by many like benefactions.

Pharmacology and Therapeutics.

GEOSOTE.

GEOSOTE is the name given to a combination of valerianic acid with creosote which has been employed in practice by Dr. Rieck. It is an oily liquid, with a sweetish taste, but without the burning character of creosote, and when injected under the skin in doses of from fifteen to thirty grains the smarting sensation produced soon passes off. For children from two to eight years of age four to ten drops may be given in mucilage or in a spirituous solution. Adults can take it in capsules containing thirty grains, one, two or three capsules being a dose. It appears to be a decided tonic in debility and chlorosis and to be useful in intestinal catarrh and in infantile diarrhœa where calomel, castor oil, and tannin have failed. In the pulmonary catarrh of adults, as well as of children, it is particularly valuable, as of seventy-six cases of phthisis only thirteen are reported as not having derived benefit from it. Indeed, Dr. Rieck has never seen any other remedy productive of so much good. Similarly, it has been satisfactorily employed by the hypodermic method in tuberculous glands, joints, and bones.

CREOSOTE IN HABITUAL CONSTIPATION.

According to Dr. Vladimir de Holstein, of Paris, who writes in the *Semaine Médicale*, one of the best remedies for habitual constipation is to be found in creosote, at least if administered according to a certain plan which he describes. He was first led to employ this drug for constipation from observing its effects on the intestinal functions of a chlorotic young woman for whom he had prescribed it after ferruginous and arsenical preparations had been given for some time without having any appreciable effect on her general condition. Dr. de Holstein's belief was that chlorosis often depends on some auto-intoxication having its origin in the bowels, and he therefore thought that perhaps creosote, being capable of destroying noxious micro-organisms in the digestive canal, might lead to an improved condition of blood. The patient constantly suffered from the most obstinate constipation, which had been treated without very satisfactory results by means of abdominal massage and oil enemata. To Dr. de Holstein's surprise, after the creosote treatment was commenced a daily evacuation was obtained without any artificial assistance. Since then he has employed similar treatment in a large number of cases of habitual constipation and so far has not come upon a single one in which either the creosote was not well borne or in which it did not prove successful. Beech creosote is always used, and he does not approve of pills, perles, or solutions containing spirit, but always administers it in drops in a glass of wine and water, milk, or plain water twice a day after meals. In order to accustom the patient to the burning taste of the creosote it is best to commence with a single drop and gradually to increase this to seven or eight or even more if that should prove insufficient. The treatment should be persevered in for several months and is said to have no ill effects on the teeth or other organs. Of course there is no reason to suppose that creosote possesses purgative properties, its effect on constipation appearing to be due to its neutralising some intestinal toxin which in patients with chronic constipation paralyses the action of the digestive canal.

KOLANIN, THE STIMULATING PRINCIPLE OF THE KOLA NUT.

Dr. Knebel, working in the Pharmaceutical Institute of the University of Erlangen under the direction of Professor Hilger, has found that the active principle of the kola nut is not, as has been supposed, an alkaloid, but a glucoside, which he has isolated and had made into tabellæ containing three grains in each. These appear to exert a better and more stimulating effect than other preparations of the nut. Dr. Dornblüth, of Rostock, has recently published an account of his observations on their employment in practice, having first satisfied himself by experiments on his own person that he might safely prescribe this so-called kolanin. After a more than usually arduous and fatiguing time of seeing patients he found that a single tabella relieved the feeling of exhaustion in a few minutes in a way that caffein had never been able to do, and, moreover, without leaving any unpleasant exciting effects as the latter drug generally did. With patients he found, too, that it relieved many who complained of exhaustion, and left no unpleasant after-effects in the way of lassitude. In the cardiac weakness of neurasthenics, where the pulse is small and fluttering and the patient feels very faint, kolanin generally produces an excellent effect. In two patients with organic heart disease complicated with kidney trouble, where digitalis had not proved as successful as might be desired, kolanin given in three-grain doses every half-hour soon caused a marked improvement. In migraine of a vaso-paralytic character it was also useful, as well as in headaches due to excitement, overwork, or alcohol.

HELOUAN, ITS CLIMATE, WATERS, AND RECENT IMPROVEMENTS.

BY W. PAGE MAY, M.D., B.SC., M.R.C.P. LOND.,
FELLOW OF UNIVERSITY COLLEGE, LONDON; FORMERLY MEDICAL REGISTRAR AND PATHOLOGIST TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

HELOUAN or, as it is sometimes called, Helouan-les-Bains is a small town situated on one of the slopes of the Mokattam Hills, in latitude 30° N., and is surrounded on all sides by the Arabian Desert. It is an artificial oasis sixteen miles due south of Cairo, 200 ft. above the Mediterranean, and 140 ft. above the eastern bank of the Nile, which is about three miles distant. Assouan lies 600 miles further south and Luxor about 450 miles. Helouan has a population of 7000, and covers about two-thirds of a square mile. It was planned and laid out under the direct auspices of the Egyptian Government. The late Khedive, H.H. Tewfik Pasha, built a large palace there and chose it as his favourite residence, an example quickly followed by many of the Egyptian princes and pashas.

Communication.—Trains run from Helouan to Cairo in from twenty-five to forty-five minutes, and there is a train each way on an average every hour. Cairo is five or six days from London by the overland route; it is twelve or fourteen days by the long sea route. There is a telephone between Helouan and Cairo.

Soil.—Helouan stands on a mixture of sand and gravel which is continuous with the surrounding desert. To the east gradually rise the Mokattam Hills, which consist largely of early tertiary nummulite limestone and pass without a break into the mountains and valleys of the Arabian Desert. The rounded summits of the hills in the vicinity of Helouan rise to a height of 1200 or 1500 ft. and alternate with broad plateaus or winding valleys. To the north and south are undulating slopes of the desert the surface of which consists of sand or gypseous saline conglomerate, offering unrivalled opportunities to the equestrian. A few miles to the north also are the remains of a sea beach through which the railway to Cairo has been cut. And within an hour's ride past occasional inscriptions, are the huge quarries of Turah and Massarah, from which the stone was taken for building many of the Pyramids. To the west of Helouan the desert slopes gradually down for two and a half or three miles to the narrow strip of cultivated land which fringes the Nile. On the other side of the river lies the town of Bedrashein. A large weekly market is held there, and it is one of the towns in which the primitive life of the Egyptian fellaheen can be well seen and studied.

Just beyond Bedrashein are the ruins of Memphis, founded more than 4000 years B.C. by Menes, the first historic king of Egypt, while an hour's further donkey ride brings the visitor to the step Pyramid and Sakkara with its beautiful and vivid remains of the Egyptian civilisation some 3000 and 4000 years B.C. The character of the situation of Helouan and of the view from it is sufficiently evident from the fact that it includes no fewer than twenty pyramids—namely, those at Gizeh, Abu Roash, Sakkara, and Dashur, the Nile and its valley, with cultivated land and palms, the desert, the Arabian hills, and Cairo in the distance.

The climate of Helouan.—The above brief account of the situation of Helouan will suggest the character of its climate. That which prevails in summer is of no importance, since Helouan as a winter resort is the special subject of this article. The season for Europeans may be said to last from the beginning of November to the middle (or end) of April; its termination partly depends on the question whether the visitor is in search of health or interest or of both.

Digitized by Google

The following account of the climate is based upon the results of my own observations made daily at 9 A.M. and 9 P.M. The instruments had been chosen with care, and I believe that the facts ascertained are thoroughly trustworthy. The barometer was of the Kew pattern, and the maximum and minimum thermometers, the wet and dry bulb instruments, the soil thermometers (4 ft. and 1 ft.), and those with black bulb in vacuo for solar radiation were all by Casella, and had been tested and approved at Kew Observatory. The rain gauge had a diameter of 5 in. The Robinson's Anemometer and Jordan's Sunshine Recorder were by Negretti and Zambra, and worked admirably. The self-recording thermometer and hair hygrometer were made by Richard Frères, of Paris, and the chart for each was changed every Monday at 9 A.M. The shade instruments were placed in a Stevenson's screen of the pattern approved by the Royal Meteorological Society—viz., double wooden roof, with double louvred sides, &c.—on the large flat roof of the hotel 40 ft. above the ground.

Air.—The air at Helouan is that from the desert, and usually described as quite free from germs and organic matter of all descriptions. It must in any case be remarkably low in those constituents. (Some observations being made on this point I hope to bring forward on another occasion.) From the fact that the desert surrounds Helouan the air must be remarkably pure, dry, bracing, and invigorating; and as there is no doubt that one of the chief factors in the beneficial influence of a climate is the aseptic condition of its air, the importance of the practically sterile condition of the desert air at Helouan can scarcely be sufficiently emphasised. Anyone who has experienced the effect of breathing the desert air on a fresh morning will vividly remember what a light-hearted, buoyant feeling it produces, combined with a desire for physical exercise.

Sunshine (see Table I.).—The influence of sunshine in promoting natural processes is as important in the case of animals as in that of plants. Its powerful effect in destroying bacteria is well known but not sufficiently utilised. To take one example only, Koch has shown that whereas in diffused daylight tubercle bacilli live for five or seven days direct sunlight kills them in at most a few hours, and not infrequently in a few minutes.

TABLE I.—*Showing the Amount of Sunshine at Helouan.*

—	Actual sunshine.	Daily sunshine, average.	Morning sunshine, average.	Afternoon sunshine, average.	Greatest daily amount.	Smallest daily amount.	Solar radiation black bulb in vacuo, average.

March ...	291 12	9 24	4 58	4 26	11 45	1 50	151·6
Totals	1221 37	7 57	4 14	3 51	—	—	143·6

The average sunshine at Helouan during the last winter (November to March) was nearly eight hours a day, and 1221 hours 37 minutes of sunshine were recorded for the five months, of which the greatest amount (291 hours) in one month occurred in March and the least in January (213 hours). It is interesting to note that on an average for the winter there were twenty-three minutes more sunshine registered daily before midday than after, whereas later it will be seen that there was 75 per cent. more wind through the day than through the night. Perhaps the most striking evidence of the character of the climate was the fact that not a single day occurred without some sunshine. Moreover, the atmosphere is peculiarly transparent to the sun's rays, both luminous and chemical, as measurement of the actinic effects of the light demonstrates in a very precise way. The average maximum solar radiation as registered by a thermometer with its blackened bulb in vacuo was 143°. The heat in the sun was usually most agreeable, and many people preferred to wear an ordinary straw hat or cloth cap without any other protection, and were able to do so without inconvenience.

Temperature (see Table II.).—It will be seen from the tables that the temperature during the winter months at Helouan is well suited for invalids. It is true that there is a distinct difference between the mean maxima and minima for each twenty-four hours, but the difference (21°) is not a disadvantage and is pleasant rather than otherwise. This daily range of temperature, however, is less at Helouan and Cairo than at Luxor or Assouan, and is decidedly less than in the Alps and

in Colorado and many well-known health resorts. Also, the comparative equability of temperature at Helouan is still more marked if one takes the range of extreme temperatures—Davos giving 10·5° more and Colorado Spring 26·3° more variation as the average for each month (see Table II.). Taking the invalid's day as lasting from 9 A.M. to 9 P.M., it will be seen that he can live out of doors in pure desert air from the beginning of November to the end of March in an average temperature of from 60° F. at 9 A.M., increasing steadily to 72° at about 3 P.M., and returning slowly to a temperature of 61° at 9 P.M. At night the average minimum for the same period is 50·9° F., and therefore, sleeping with open window, there would be no risk of catching cold. Indeed, owing to the retention of heat by the walls of the room the lowest temperature in the room itself would be about 5° or 6° higher.

So much is heard of a sudden fall in the temperature at sunset that a passing remark is necessary. At Helouan, as in desert climates generally, no sudden drop in the temperature occurs as is so frequent elsewhere; and that this is so a glance at the actual temperature chart for the four days, Jan. 6th to 9th inclusive, 1897, will show. The temperature there is self recorded, and given accurately for every moment in the week, yet there is no appreciable drop at the time of sunset, but the temperature gradually falls from the daily maximum to the minimum. Indeed, not only is this true of Helouan, but at a discussion of the Royal Meteorological Society on Dec. 16th, 1896, Dr. Marcet and Dr. Theodore Williams stated that they "experienced no appreciable chill at sunset" even at Luxor or in Egypt generally.

It is important to notice that, as is well known, the temperature of drained land is more equable than that of undrained,[1] and at Helouan the 9 P.M. temperature of the soil four feet in depth only showed an increase of less than one-fifth of a degree over the 9 A.M. temperature. In December, January, and February the difference was even less (see Table II.) and scarcely appreciable. During the winter this four-foot temperature scarcely varied from hour to hour or day to day, and from the beginning of December, when it stood at 75°, it descended gradually until it reached 68·8° at the end of January, and rose gradually to 71·8° at the end of March. At no time did it exceed these extremes. It will be noticed that the temperature of the soil four feet below the surface is above the average in other places, and this peculiarity is without doubt due to the conditions which cause, or are associated with, the thermal springs.

Digitized by Google

Temperature chart showing gradual fall from about 3 P.M. to 7 A.M., but no sudden drop.

Humidity (see Table III.).—The mean of the 9 A.M. temperature for the five months Nov. to March was 60·5° and the mean of the evaporation temperature (wet bulb thermometer) was 53·3°, whereas the mean of the 9 P.M. temperature for the same period was 61·2° and of the wet bulb thermometer was 53 6°. These results were obtained by eye observations of the standard instruments at the hours named, and give by calculation with Glaisher's tables a relative humidity at 9 A.M. of 60 per cent. and 9 P.M. of 59 per cent. The relative humidity as indicated by a recording hygrometer has daily maxima and minima for the same period of 84 and 30 per cent. respectively. Thus, again, taking the invalid's day as from 9 A.M. to 9 P.M. a visitor at Helouan could breathe desert air from November to April inclusive, containing on the average at that period of the twenty-four hours only between 30 and 60 per cent. of moisture (relative humidity).

Wind (see Table IV.).—The mean numbers given by the Robinson anemometer were for the five months, November to March, 20·75 between 9 P.M. through the night to 9 A.M., and 36 45 for the mean twelve hours 9 A.M. to 9 P.M. That is, there was an increase of about 75 per cent. of wind during the day. It will be seen on reference to the table that February was the most windy month, March rather less windy, and November least.

* Less than half an inch during the five months.
† In one evening, Dec. 2nd.

Dust.—So much prominence has been given by some writers to the dust in Egypt that a few remarks are necessary. It may be divided into two chief kinds, that arising from the dried cultivated land or towns and that from the desert. The latter has a much higher specific gravity, and is in larger granules than the former. If one gives a kick into the desert soil so as to send up a small cloud, dust particles will be seen to remain in the air for a few seconds only and rapidly settle on the earth again; but if one performs the same little experiment with the dried soil of the cultivated land the particles of dust remain for several seconds, or even minutes, floating visibly in the air. Hence in those parts of Egypt (viz., by the river and in the cultivated land chiefly) where dried agricultural soil predominates dust in the air is much more common than in the desert, and from the golf links at Helouan clouds of dust can frequently be seen driving along by the river, while the air at Helouan remains perfectly clear. As Professor Flinders Petrie has pointed out, the occasional strong winds raising dust almost invariably originate to the west of the Nile, and expend a great deal of their force in crossing to the eastern bank. Hence dust is less abundant on the eastern bank.

Possibly one reason for the erroneous idea prevalent as to the amount of dust in Egypt is that the windiest season—

Digitized by Google

viz., the latter half of February and beginning of March—is precisely the time of year at which most pleasure-seekers visit Cairo, and after a flying visit they depart with the idea that the conditions they have seen locally for a few days must be prevalent throughout the country for the whole season.

Rain (see Table IV.).—Less than half an inch of rain fell in the five months (November, 1896, to March, 1897). The exact amount was $\frac{47}{100}$ in., and of this $\frac{43}{100}$ of an inch fell in one evening (Dec. 2nd). Therefore, as far as invalids are concerned, the winter was practically rainless.

Thermal waters.—The climate is not the only physical advantage which Helouan offers to those in search of health. It also possesses valuable thermal springs[2] giving in abundance three kinds of waters—viz., sulphur waters, saline waters, and chalybeate waters. There are several springs, but they may be roughly divided into three groups—a group near the present baths, consisting chiefly of sulphur water; a group in the desert, about a mile to the north of Helouan, consisting simply of saline water; and a few springs to the west of the Khedivial Palace containing chalybeate water. The thermal mineral waters of all kinds are in abundance. Three of the sulphur springs near the baths are reserved exclusively for use at the bath establishment; one of the springs gives twelve gallons of sulphur-saline water a minute, and is running to waste day and night; the other two give similar quantities and are in the bath establishment itself. The temperature of the water in the spring is 90° F. Through the kindness of Messrs. Suares I was enabled to obtain an analysis of the water from Professor Attfield, F.R.S., and his analysis (given below) coincides with that of Professor Gastinel Pasha, made several years ago.

TABLE V.—*Analysis of the Sulphur Water of Helouan-les-Bains by Professor J. Attfield, F.R.S. (Oct. 30th, 1896).*

Dissolved solids.	Grammes per litre.	Grains per gallon.
Potassium chloride...	0·2923	20·4610
Sodium chloride	5·0690	354·8300
Calcium sulphate	0·0694	4·8580
Calcium carbonate...	0·8250	57·7500
Magnesium sulphate	0·5069	35·4830
Iron and alumina	0·0160	1·1200
Silica	0·0290	2·0300
Sulphuretted hydrogen	0·0918	6·4260
	6·8994	482·9580

The above weight of sulphuretted hydrogen gas corresponds to rather more than sixty cubic centimetres in one litre, or more than two cubic inches in one imperial pint. The sulphur water of Helouan-les-Bains is therefore practically identical in strength as regards sulphur with the celebrated Montpellier sulphur spring of Harrogate.

Analytical data.—Grains per gallon: potassium, 10·7100; sodium, 139·5100; calcium, 24·5280; magnesium, 6·9300; iron and alumina, 1·1200; silica (SiO_2), 2·0300; sulphuric radical (SO_4), 31·9830; chlorine, 225·0710; carbonic radical (CO_3), 34·6500; and sulphuretted hydrogen (H_2S), 6·4260. Total dissolved substances in grains per gallon—that is, parts per 70,000 parts—482·9580.

TABLE VI.—*Analysis of the Saline Carbonated Iron Water of Helouan-les-Bains, by Professor Attfield, F.R.S. (Oct. 30th, 1896).*

Dissolved solids.	Grammes per litre.	Grains per gallon.
Potassium chloride...	0·2862	20·0340
Sodium chloride	4·7050	329·3500
Calcium sulphate	0·7340	51·3800
Calcium carbonate...	0·5157	36·0990
Magnesium sulphate	0·3613	25·2910
Iron and alumina	0·0150	1·0500
Silica	0·0350	2·4500
Total dissolved solids	6·6522	465·6540

[2] The Advantages of Dry Desert Air and the Application of Mineral Waters in Gout, Rheumatism and Early Phthisis.—Dr. Hinsley Walker, THE LANCET, October 7th, 1893.

Analytical data.—Grains per gallon: potassium, 10·4860; sodium, 129·500; calcium, 29·5400; magnesium, 5·2920; iron and alumina, 1·0500; silica (SiO_2), 2·4500; sulphuric radical (SO_4), 56·2800; chlorine, 209·3980; carbonic radical (CO_3), 21·6580. Total dissolved solids, in grains per gallon, 465·6540.

There is also a simple saline water containing 4·9690 grammes per litre, or 347·8300 grains per gallon of similar salts. In addition to this there are several springs yielding water in abundance, but not yet carefully analysed.

Baths.—The bath establishment in present use is the property of the Egyptian Government, who last summer granted a concession of the same for a term of forty-five years to Messrs. Suares on condition that certain stipulated improvements be made. On taking over the old bath establishment it was found that immediate improvements and alterations were necessary, and these were carried out with due dispatch. New pipes throughout and heating apparatus (boilers and thermas) were set up. A tower was built supporting two large reservoirs thirty-five feet high, so as to supply hot sulphur water and cold sulphur water at a sufficient pressure for the various douches. An electric bath was fitted and also a large room constructed for the inhalation of sulphur vapour, as at Bath, Marlioz, &c. (so-called dry inhalation). Also sulphur inhalation steam sprays were installed for use in throat complaints, &c. Hence at the present moment immersion baths, douches of all kinds, needle baths, electric baths, hot air baths, inhalations, and pulverisations can be administered, and the so-called Aix- (massage) douche is given by skilled European attendants. It has, however, been decided to erect an entirely new bath establishment to supplement the old one. The plans of the new bath establishment have been drawn up on the basis of the most modern balneological and hygienic ideas, and have been (according to the terms of the concession) submitted to the enlightened Public Works Department of the Egyptian Government under Sir J. E. Garstin, K.C.M.G., and approved. H.H. the Khedive also, after a careful examination of the plans, expressed his entire approval of them. The new baths are already in process of construction and probably will be completed during the present winter. They will contain a spacious hall with entirely separate entrances and accommodation for ladies and gentlemen, waiting-rooms, cooling-rooms, twenty-six simple immersion baths, eight large combination bathrooms, each containing an immersion, a needle bath, douches and sprays of all kinds, whilst opening into each combination-room directly will be three separate spacious dressing-rooms, so that the bathers need never be hurried after their bath. Also, accommodation for hot air and steam (local and general), electric baths, inhalations and pulverisations, and all the most modern and necessary appliances will be provided. Adjoining the bath establishment is a large swimming bath of sulphur water, about 70 yards long and 25 broad, through which fresh sulphur-saline water is flowing day and night. It is divided into two portions, one being reserved for ladies and one for gentlemen.

Hence at present Helouan offers during the winter months many exceptional advantages to those in search of health or rest and change. The two chief factors of course are the climate (with the various influences included under that term) and the thermal waters, but to them should be added the powerful influence exerted on the body through the mind by the unfamiliar surroundings and the unique interest of Eastern life and the remains of Egypt's former greatness. The climate, as pointed out above, is a desert climate, and therefore dry and invigorating, and during the winter months almost ideal from the point of view of the seeker after health.[3]

INDICATIONS.

It is evident that by residence in such a warm, dry, equable climate, with air unusually free from dust and germs, with abundance of sunshine and practical immunity from rain, mist, or snow, with healthy mental occupation and surrounded by the resources of civilisation, sufferers from early chest trouble, enlarged glands, scrofula, renal disease, and albuminuria are likely to derive important benefit. Such conditions will obviously be very efficacious also to patients convalescent from severe illness and to those who are anæmic and debilitated or in dubious health. Moreover, such a decided change as Helouan offers in physical and mental surroundings is of the greatest help in cases of functional diseases of the nervous system, especially if

[3] Egypt as a Health Resort, by Dr. Sandwith.

Digitized by Google

previously associated with overwork or mental strain. The thermal waters (sulphur, saline, and chalybeate), as pointed out above, may be used either internally or externally or combined. Judiciously employed they certainly exert an eliminative action and are of distinct benefit in cases of gout, lithæmia, and allied conditions. They are useful also in cases of bronchial, laryngeal, and pharyngeal catarrhs, stasis of the portal system, and abdominal plethora, whilst sufferers from dyspepsia, engorgement of the liver and pelvic organs are often indirectly benefited, especially if their troubles are associated with a gouty or rheumatic diathesis. Patients with rheumatoid arthritis distinctly improve, and, as Dr. Bannatyne states, Egypt is *par excellence* the place for sufferers from that disease to winter in. Conditions such as sciatica, rheumatism, stiff joints, or arthritis, whether affecting one joint or more widely diffused, undergo most marked improvement at Helouan, and in these cases it is difficult to apportion the amount of advantage derived from the waters and the peculiar warm, dry desert air. Also, cases of chronic skin disease and special cases of debility are frequently much improved or cured by the use of the waters.

To sum up, Helouan is unique in Egypt in three important particulars and in what follows therefrom—viz., in being surrounded on all sides by the desert, in being not on the level of the Nile, but 140 feet above it, and in the possession of thermal, sulphur, and muriated saline waters; moreover, so far as I know, no other resort within several weeks' journey of London possesses a combination of thermal sulphur waters, &c., and a warm, dry climate during the winter months.

In conclusion, I can corroborate the testimony of Dr. Fenyes, who has been for some years in practice at Helouan, and who has not seen a single case of typhoid fever, diphtheria, scarlet fever, dengue, malaria, or so-called specific disease, which had originated in Helouan.

OTHER RESIDENTIAL PLACES IN EGYPT COMPARED WITH HELOUAN.

Assouan.—This town, which is 600 miles further south and 35 miles from the tropics, is situated on the Nile bank. It has a mean temperature (from December to March) of 8·4 degrees warmer than Helouan,[4] but is much less equable, the mean daily range of temperature being 6·2 degrees more; the range of extreme temperature for the four months is also greater, being in the mean 50·4°, as against 40·5°.[5] As Assouan is warmer the relative humidity is less; the mean is given by Dr. Canney as 40·5°, against 54·2° at Helouan.[6] The mean absolute humidity, however, is only slightly less at Assouan—viz., 28° at Assouan and 30° at Helouan[7] (calculated as grains of aqueous vapour per 10 cubic feet of air). The results for the two relatively drier months, November and April, at Helouan are not given. It is interesting to note that the absolute humidity at Assouan in February was the same (28°) as at Helouan in January, and was the same (29°) at Assouan in March, as at Helouan in February. The late Dr. Jalland worked an anemometer which I placed at Assouan, and the results he sent me when compared with those obtained by an identical method at Helouan confirm the general idea that there is distinctly more wind at Assouan; also, there is more sunshine. The season at Assouan is shorter—viz., from the beginning of December to about the middle of March. The hotel, with accommodation for seventy people, is quite comfortable and has a dependance in the shape of a disused steamer.

Luxor.—This place, which is 450 miles south of Helouan and situated on the Nile bank in cultivated land, has more sunshine than Helouan, and in December to March is 3·6° warmer in the mean, but is much less equable, having a mean daily range of temperature of 6·2° more. The range of extreme temperature is also greater in the mean, being 49·6° as against 43·5°.

The relative humidity is higher—viz., 56·9, as against 54·2, and the absolute humidity is greater—viz., 31 (grains per 10 cubic feet) at Luxor, as against 30 at Helouan. There is less wind than at Assouan or Helouan. The chief hotel is comfortable, but stands in a luxuriant garden and is largely surrounded by the native village.

Mena House.—This is situated nine miles by road from Cairo, just above the level of the high Nile and 100 yards from the cultivated land. The temperature is in all respects much the same as at Helouan, and there is rarely a difference of 1°F. The moisture in the air is, however, distinctly greater both relatively and absolutely. Relative humidity (December to March) had a mean of 68·9 and absolute humidity gives 35 (grains of aqueous vapour in 10 cubic feet of air) as against 30 at Helouan. It is slightly more windy than at Helouan.

Cairo.—Cairo is situated on the level of the Nile, and has a population of about half a million people. The temperature is much the same as at Helouan. Humidity, both absolute and relative, is greater than at Mena, and still more so, therefore, than at Helouan. Owing to the changes produced in the soil and atmosphere by the High Nile it is very distinctly less healthy at the beginning of the winter than later. Its attractions are chiefly social. As an Eastern town with its commingling of Eastern and cosmopolitan life, each moment unfolding the scenes of the Arabian nights, with its mosques, its citadel, its absolutely unique museums, its attractions innumerable, its official and military elements, to say nothing of polo, races, cricket, golf, tennis, and military tournaments, few places can compare with it in its season. For those requiring such attractions or suffering merely from over-worked nervous systems or such disorders as neurasthenia it can be strongly recommended.

Accommodation, &c.—In Helouan there are two chief hotels, boarding-houses, and many villas on hire. The Helouan Hotel was built five years ago. The rooms are unusually lofty, large, and well-ventilated, and the hotel is comfortably furnished. It has electric light in every room, a large, well-appointed dark room for photographers, English and French billiards, and an excellent lending library, with books in English, French, and German. The cuisine is at least equal to that of the best hotels in Cairo. The sanitation is beyond reproach. Pension and room from 50 piastres—i.e., just over 10*s.* a day. The Grand Hotel des Bains adjoins the bathing establishment, and was entirely renovated last year. It accommodates about fifty visitors, and is well appointed in every way. Its sanitation, new throughout, has been approved by the Sanitary Department of the Egyptian Government under Dr. Rogers Pasha. Pension and room from 32 piastres—i.e., about 6*s.* 6*d.* a day.

The water-supply is constant and excellent. The water is taken from the Nile about eighteen miles above Cairo and pumped up to the town reservoir. For drinking and bedroom purposes in the two hotels mentioned it is filtered through Pasteur filters and is always in abundance.

At Helouan there are now good golf links in the desert five minutes' walk from the Helouan Hotel, and a golf club house is being built. Asphalt and cement lawn tennis courts, croquet, bowls, &c., horses, camels, or donkeys can always be obtained (or, if preferred, hired from Cairo and stabled in Helouan). Sand carts for driving into the desert, &c., can be hired from the hotels. Helouan forms a very convenient starting point for visiting the Pyramids and tombs of Sakkara, Dashur, &c., and the expeditions into the desert are interesting at first, later fascinating, and always health-giving. Cairo with its unique attractions and environs can be reached in twenty-five or at most forty minutes, and, as has been already stated, there is a train each way about every hour.

By the river there is the usual shooting obtainable in Egypt—viz., quail, snipe, and wild fowl, whilst the fauna of the desert though scarce fully repay the chase. The river, about three miles distant, can be reached by bicycling or driving or in the special trolley which runs over an old rail. And on the river the hotel steam launch can be hired at 30*s.* a day, or 20*s.* the half-day. Sailing boats are also to be had. An Egyptian military band plays every Sunday afternoon and evening at Helouan, and not infrequently (mostly on Thursdays) an English military band plays in the quadrangle of the Helouan Hotel.

At Helouan there are three posts a day, five mails a week from England (transit from five to seven days), and telegraphic and telephonic communications. The latter with all parts of Cairo is constantly available.

It may be interesting to compare the following meteorological observations with those at Helouan. Only the averages are shown, and there are no sunshine records except

[4] Dr. Leigh Canney (Quarterly Journal of the Royal Meteorological Society, April, 1897, p. 192) placed a self-recording thermometer and hygrometer in a screen at each of the following places—viz., at Assouan (worked by Dr. Longmore and Dr. Jalland), at Luxor (worked by himself), at Mena (worked by Dr. Bentley and Mr. Hichens), and at Helouan (worked by the electrician, Monsieur Douat). His temperature and moisture results thus obtained are quite the best comparative meteorological work yet done on the above places.

Welbeck-street, W.

THE VACANCY IN THE GENERAL MEDICAL COUNCIL.

MR. VICTOR HORSLEY'S CANDIDATURE.

MR. VICTOR HORSLEY had a crowded meeting at the rooms of the Medical Society of London, 11, Chandos-street, on Friday afternoon, Oct. 1st, to hear his views on medical reform.

Mr. STAMFORD FELCE, in introducing Mr. Horsley to the meeting, said it was a pleasure to support Mr. Horsley in anything that he did because he always did it so zealously and painstakingly. The work that Mr. Horsley had done already for the profession in connexion with the Medical Defence Union would alone fit him for the larger sphere of usefulness he now sought to fill. Sir Walter Foster had relinquished his post on the General Medical Council and he had shown no cause in his address why he should now have altered his mind.

Mr. VICTOR HORSLEY expressed his regret that he had been unable to arrange the meeting so that a report of it could appear in the medical press of last week. He was before them to-day wishing to enter the General Medical Council for a very specific purpose. His experience in the work of the Medical Defence Union had shown him clearly that unless the work of medical defence had some sort of representation on the General Medical Council all those evils which pressed most heavily at the present time on the profession would remain unrelieved as they had done during the last decade. As he had already explained in his address he had much experience in the work of medical defence, and if he was returned as a Direct Representative to the General Medical Council he would exercise that knowledge and would at the same time be ready to receive suggestions and help from his former colleagues. Among the reforms which seemed to him most urgent was undoubtedly the reform of the constitution of the Council. This came first, although it seemed to fall in importance behind other questions which dealt more immediately with the actual lives of medical men. Yet it would be clear to everyone that unless the great principle of political representation was given more scope in the constitution of the Council they could not hope for any rapid advance in practical reforms. Mr. Horsley then referred to the over representation of the universities and corporations as compared with the representation of the profession directly, and laid stress on the fact that this question, one which concerned the interests of the general practitioner as opposed to those of the consultant, could only be solved by making direct representation also to some extent geographical representation. He would strive to make representation topical, representative of divisions of the country, in order that the candidate for a seat on the Council might have full advantage of his local reputation. With regard to the reform of the by-laws of the General Medical Council Mr. Horsley claimed that the Council had power under the Privy Council to draw up by-laws for the conduct of its own business. Last year he had ventured to draw attention at the meeting of the British Medical Association at Carlisle to the work of the penal committee of the Council, and especially to the really extraordinary by-laws under which that committee was acting, because he considered that their by-laws conferred an exceedingly dangerous power upon the President and the legal adviser of the Council. The justice of his contention had since been acknowledged by an alteration in the by-laws relating to the penal procedure. Mr. Horsley then went on to say that though grateful for the kind way in which his candidature had been spoken of in THE LANCET he wished at this point to refer to one error which had slipped into the enumeration of what were termed by that paper his virtues. THE LANCET said that he had made unwarrantable attacks upon the President of the General Medical Council. What he really did was, as he had always said, to show that the by-laws conferred certain powers on the President of the Council which might have evil effects. Without giving him the slightest opportunity of demonstrating the correctness of his contention the Council had condemned his action. He then published a letter in the press challenging comment in a public manner, but received no reply. Mr. Horsley then quoted from the minutes of Council certain resolutions and amendments which he held to justify his statement that the by-laws of the Council at that time were in a very dangerous condition. With reference to the past work of the Direct Representatives Mr. Horsley said that to the question, "Who among the Direct Representatives has worked most for us?" the answer was simple and certain. It was Dr. Glover, and Mr. Horsley invited those who had seen other statements made to peruse the official Minutes of the Council. They would then see that the man who had brought forward and initiated most movements in favour of reform in the Council was Dr. Glover, to whose name he would now add that of Dr. Bruce.

Referring to his advocacy of a one-portal system he had heard it stated that there seemed to be very little feeling on the subject in the profession, but he had had letters sent to him from all parts of the country drawing attention to the inequality under which men gained access to the profession, and complaining of the absence of a uniform degree. He had never been able to see the objection to the granting of such a degree. The Act of 1886 was designed to import such uniformity into our system by establishing the triple qualification of medicine, surgery, and midwifery. An attendance at a meeting of the Council would show that the representatives of the corporate bodies represented the bodies who sent them rather than the union of the portals of the profession. Referring to the question of medical aid associations Mr. Horsley said that if he were asked his views in the Council on this point he would repeat what he had stated publicly for several years, that it was a question which could only be decided by the Council itself, and from an ethical point of view under the clause which gave the Council power to deal with a practitioner whose conduct was "infamous in a professional respect." There was no doubt whatever that if a medical practitioner was brought before the Council on the charge of having employed touts or canvassers he would be struck off the register, or at any rate threatened if he did not give up the practice.

Mr. Horsley then corrected certain mis-statements that had been made by Mr. Colin Campbell and in the press concerning a statement attributed to him that £400 a year was sufficient to support a medical man, and concluded by reading to the meeting the brief statement which follows of his position with regard to the question of the registration of midwives.

As I find that considerable misconception and confusion prevails concerning the so-called "Midwives question" I beg to lay before you the following facts:—

1. Persons called midwives are at the present time and in considerable number carrying on midwifery nursing and irregular midwifery practice.

2. In recent years, but especially since 1889, when Sir Walter Foster brought forward and carried in the General Medical Council a motion urging the Government to construct and pass a law for the registration of midwives, a popular agitation had been carried on to effect this and to confer upon them what is practically a professional title and status.

3. There is also a widespread and obviously just feeling that the calamities which are caused at present by ignorant midwives cannot be allowed to continue, and the registration of the title midwife or midwifery nurse has been erroneously supposed by the General Medical Council to safeguard the interests of the public.

4. To procure safety for the public it is clear that the so-called midwives must be taught midwifery nursing, and that any person who follows the calling of a midwifery nurse without having had such teaching must be punished by statute.

5. No legislative guarantee of this kind, however, is possible unless

Digitized by Google

the names of properly taught midwifery nurses are placed on a list or register.

6. To meet the requirements of the public as laid down in the report of the Select Committee of the House of Commons, 1893, it is evident that the Privy Council will at no very distant date introduce a Bill which, to judge from the two (Lord Balfour's and Mr. Egerton's) already sent to the General Medical Council for consideration and report "as soon as possible" (*vide* Minutes G.M.C., 1897), will probably contain no safeguard either to the medical profession or the public.

7. The case of the medical profession has been gravely prejudiced by the practical adoption by a committee of the General Medical Council (of which Sir Walter Foster was a member), and subsequently by the Council, of the former of these Bills, and by its amendment in various unimportant particulars without provision of a single safeguard against the establishment and quasi-legislation of a body of unqualified practitioners in midwifery, such as the existing midwives.

8. The General Medical Council has now appointed a committee to consider Mr. Egerton's Bill; the question is therefore practically re-opened.

9. The Parliamentary Bills Committee of the British Medical Association, through a sub-committee of which I was chairman, has prepared a Bill for the teaching and regulation of obstetric nurses, which is now before the Council of the Association for consideration.

10. The point of immediate importance to the profession in this question at the present time is the strict preservation of the triple qualification in Medicine, Surgery, and Midwifery alone possessed by registered medical practitioners.

11. There are two methods of securing this, of which the first is the proposition by the Lancashire and Cheshire Branch of the British Medical Association—namely, "that every case of midwifery attended by a midwife should be seen by a registered medical practitioner within twenty-four hours of the commencement of labour." This I believe would adequately meet the case.

12. The second, however, is more fundamental in principle, and is what I should endeavour to secure acceptance by the General Medical Council and reference to the Privy Council as being a complete legislative safeguard against the attempted contravention of the Medical Acts. I propose that when any report on a Midwifery Nurse's Bill is brought forward for final adoption there shall be first adopted a Bill for the amendment of the Medical Acts to prevent the practice for gain of medicine, surgery, and midwifery by any but practitioners registered under the Medical Acts.

13. This safeguard will at the same time put a stop to the irregular practice in diseases of women and children carried on at the present time by midwives, certificated or otherwise, and chemists.

Mr. LOCKWOOD then proposed the following resolution: "That this meeting, having heard Mr. Horsley's address, pledges itself to do all in its power to secure his election as Direct Representative."

This was seconded by Dr. BENNETT, who said that he felt certain that what Mr. Horsley had promised to do he would do.

Dr. BATEMAN then read a list of letters which he had received from persons unable to be present, and asked leave to make a little personal statement. At Sir Walter Foster's meeting the other day he had felt it necessary to call attention to an article in a lay magazine which he considered to constitute a form of advertising. There ought not to be one law for the L.R.C.P. and another for the F.R.C.P.; one law for the G.P., and another for the J.P. In the current issue of the *British Medical Journal* there was an article headed "Sir Walter Foster and the *Young Man*" which said that "Sir Walter Foster has a right to complain of what we cannot but agree with him in calling an unchivalrous attack upon him on the score of an interview which has recently been published in a journal entitled the *Young Man*. This matter, we understand, was sprung upon him at the meeting without notice." This Dr. Bateman denied, explaining that Sir Walter Foster had had notice of the so-called attack. Dr. Bateman went on to say that about eighteen months ago he had been asked by the *British Medical Journal* for his assistance in a legal difficulty arising out of an ethical question. He had then, in behalf of the *British Medical Journal*, asserted that advertising was in every case unprofessional. Now the *British Medical Journal* sought to show that the interview in the *Young Man* was not unprofessional.

Several questions having been addressed to Mr. Horsley with the object of further elucidating his policy the motion before the meeting was unanimously carried.

A meeting of the Medico-Ethical Society of North-East London was held at 184, Mare-street, Hackney, on Friday, Oct. 1st, at 9 P.M., the Vice-President, Dr. C. T. Aveling, being in the chair. Mr. Victor Horsley delivered an interesting and instructive address on Medical Reform, in which he indicated clearly and concisely the changes that were necessary and how they could best be brought about. He made special reference to the Medical Act and explained fully his position with regard to the Midwifery Nurses Registration Bill, which he distinctly said he would not support until Clause XL. of the Medical Act had been amended so as to prevent midwives and midwifery nurses opposing medical men in practice. At the close of the meeting a unanimous vote was recorded in favour of Mr. Horsley's candidature for a seat on the General Medical Council.

On Saturday afternoon, Oct. 2nd, a meeting of the members of the medical profession in East Anglia was held in the Medical and Chirurgical Society's Rooms at Norwich to hear an address from Mr. VICTOR HORSLEY. Sir FREDERIC BATEMAN, M.D., presided, and there was a large attendance of medical practitioners from Norwich, Yarmouth, and other parts of the eastern counties.

Mr. VICTOR HORSLEY in the course of his address urged that the direct representatives ought to be general practitioners, and said that as such men were seldom very little known beyond their own district in order to give them a chance of election there ought to be district representation. The whole country ought to be marked out into districts, for it was not fair that all the candidates should have to appeal to the whole constituency. In this way the wants of each district could be properly represented. The last two years had seen a reform of the by-laws and of the procedure of the General Medical Council and the merit for this was due entirely to Dr. Bruce, the direct representative of Scotland, and to the Council of the Medical Defence Union. That Union had for years fought the General Medical Council on numerous points, but more especially as regarded their penal procedure. Two years ago a case occurred which revealed the fact that the President and the Solicitor of the General Medical Council had powers of an absolutely arbitrary nature. He exposed this fact at Carlisle. In an editorial article in THE LANCET it was stated of him: "He is impulsive; sometimes he is prejudiced and occasionally rather too aggressive. He is apt to be borne along with the very impetuosity of his perceptions and convictions. On one or two occasions he has allowed himself to make unwarranted charges against the President of the General Medical Council which offended not only the President but the Council." The charges he brought forward at Carlisle were published in the *British Medical Journal*, and the cases on which they were based were published at the same time. He showed that under the by-laws the President was the only person who could have done the things he complained of. The matter was taken before the Council by members of the Council sitting *in camerâ*, and they never called upon him to produce his documents, but issued an *ex-parte* statement to the effect that the President was not responsible. Immediately that was published in the *Times* he wrote to that paper a letter pointing out that the President alone and no one else could have done the things of which the Medical Defence Union complained. That letter had never been answered and never would be. The documents were in the office of the Medical Defence Union, and if necessary would be used at the proper time. The sentences in THE LANCET were written, he was sure, in all kindliness of spirit but in ignorance of the actual facts. Very great reforms had been achieved. A new set of by-laws had been drawn up by which all improper powers had been taken away from the executive officers of the Council, so that now the profession had the satisfaction of knowing that penal cases were no longer subject to the dictum of one man, but must go first before the committee and then before the Council. Mr. Horsley went on to speak of the attitude of the Council towards the questions of medical aid associations and midwives, which, he said, had been reopened. As to overcrowding in the profession, he noticed that Mr. Colin Campbell had represented that he (Mr. Horsley) had said at Manchester that £400 a year was sufficient to support a medical man. Of course that was not correct. What he said was that some had to live on that amount, and he regretted it very much. He thought it quite possible that too many students were entering the profession, and that if the preliminary examination were raised and the five years' curriculum maintained their number would be fewer. The decreasing incomes of medical men, however, were not due so much to this cause as to irregular competition, such as hospital abuses, quacks, and medical aid associations. The medical aid associations formed a question of medical ethics which ought to be dealt with by the General Medical Council; but that body consisted for the most part of men who represented corporate bodies and who would resist to the death anything that would diminish the number of graduates they turned out; therefore, they held that it was not the business of the Council to do

Digitized by Google

anything at all, but that the qualifying bodies should deal with it in a quiet way. As he was on the Senate of the University of London he would do all he could to bring the matter clearly before them. The question was a perfectly simple one, as had been shown by the Medical Defence Union long ago. No officer of a medical aid society was received as a member of the Medical Defence Union. No doubt the evils of the medical aid associations could only be remedied by the General Medical Council itself, under the clause by which if a registered medical practitioner was after due inquiry judged to be guilty of infamous conduct in a professional respect his name should be removed from the Medical Register. The clause gave the Council no power to reprimand only, but they sometimes did so in an indirect way, and in any amendment of the Medical Act that power would be demanded. He feared, however, the General Medical Council had lost prestige with the Privy Council. As there had been gross misrepresentation of his views on the midwifery question, he had issued a circular upon the subject. He was not pledged to support the registration of midwives. If the General Medical Council was not brought to a sense of the dangers and difficulties of the position the medical profession would soon have another system of unqualified practice to contend with. Undoubtedly midwifery nurses must be taught, but they must not be permitted to treat mothers and children as they so frequently did. This evil, of course, would be accentuated if these nurses had a registered title. The Lancashire and Cheshire branch of the British Medical Association proposed that every case of midwifery attended by a midwife should be seen by a medical man within twenty-four hours of the commencement of labour, and this safeguard had been accepted by Mr. Egerton in his Bill on the subject. This would retain the moral position the profession possessed, but he felt they ought to go deeper and bring about an amendment of the Medical Act before the Midwifery Nurses Bill was brought in. The profession was suffering a great deal from the irregular practice of quacks, and that was to be stopped. He did not believe that the members of the General Medical Council were acquainted with the Act under which they were brought together and which they practically had to administer. It would be a simple matter to reform the constitution of the Act and to increase the direct representation. Mr. Horsley went on to speak in detail of the clauses of the present Act and to point out certain abuses connected with their interpretation.

The CHAIRMAN said the qualifications for the post sought by Mr. Horsley were that he should be well in touch with his profession and that he should be of sufficient social and scientific standing to enable him to speak with something like authority on the General Medical Council. He thought Mr. Horsley possessed these qualifications.

Mr. ALLEN moved: "That this meeting, having heard Mr. Victor Horsley's statement, expresses confidence in him and promises to use its best efforts to ensure his return as one of the Direct Representatives of the General Medical Council."

Dr. BEVERLEY seconded the motion.

Mr. WYLLYS, Mr. WHITTAKER, and Mr. THOMAS having made some remarks, the motion was adopted.

A vote of thanks to the Chairman was carried and this concluded the proceedings.

SIR WALTER FOSTER'S "COLLEGE REFORM" SUB-COMMITTEE AND MR. VICTOR HORSLEY'S CANDIDATURE.

A whip has been issued by the "College Reform" Sub-committee of Sir Walter Foster's Election Committee claiming support from the profession for Sir Walter Foster as the only candidate in favour of a certain reform programme. It is to be regretted that this whip was issued, and we are sure that Sir Walter Foster will share this feeling with us, inasmuch as Mr. Horsley had actually replied to Mr. George Jackson, one of the signatories of the whip and of the programme, in the following terms:—

COPY.

25, Cavendish-square, W., 4th Oct., 1897.

DEAR MR. JACKSON,—I agree with all the Reforms mentioned in the circular you kindly send me, and though some are plainly impossible of attainment for a long period I would use every effort to press them forward.

May I add that I cannot see that our views as to what is urgently required to further the interests of the profession are in any degree divergent.

And remain, yours sincerely,

George Jackson, Esq., F.R.C.S. VICTOR HORSLEY.

The sub-committee are, we understand, giving what publicity they can to Mr. Horsley's favourable reply, but manifestly their hasty and inaccurate whip may have misled many voters inasmuch as voting commenced last Monday.

THIRTY-NINTH ANNUAL REPORT OF THE GENERAL BOARD OF COMMISSIONERS IN LUNACY FOR SCOTLAND.

THE number of lunatics under official cognisance in Scotland on Jan. 1st, 1897, was 14,500. This represents a total increase for the year 1896 of 407, as compared with 241 in the previous year. Between Jan. 1st, 1896, and Jan. 1st, 1897, the following increments took place among the insane in Scottish asylums. The population of the Royal and District Asylums shows an increase of 17 private patients and 502 pauper patients. In private asylums there is a decrease of 7 patients; in parochial asylums a decrease of 109 pauper patients; in lunatic wards of poor-houses an increase of 11 pauper patients; in private dwellings an increase of 2 private patients and a decrease of 33 pauper patients. All patients located in the above-mentioned establishments are termed registered lunatics, and the total increase of this class during 1896 was 383, of whom 12 were private patients and 371 pauper patients. The changes in the number of non-registered lunatics are indicated by the following figures. The number of insane criminals in the lunatic department of Perth Prison shows an increase of 5, and in the training schools for imbecile children there is an increase of 3 private inmates and 16 pauper inmates.

The table which records the number of admissions of registered lunatics into establishments, after deducting transfers, shows that the number of private patients admitted last year was 482, or 33 fewer than during the preceding year, and that the number of pauper patients admitted was 2645, being 111 more than in 1895; 87 voluntary patients were admitted into asylums with the sanction of the Board. The Commissioners continue to regard the provision of the law which permits the admission of patients without certificates as satisfactory, and they state that nothing has occurred to indicate any difficulty or disadvantage traceable to the presence of this class of patients in asylums. During 1896 the number discharged recovered was 1340; of these, 209 were private patients and 1131 pauper patients. The number of private patients who died in establishments during the year was 131, which is 6 more than in 1895; the number of pauper patients who died was 721, being 93 less than in the preceding year. The rate of mortality per cent. was for private patients 6·8 and for pauper patients 7·9. General paralysis, phthisis, heart disease, and senile debility were the most frequent causes of death; in this connexion it is worthy of mention that no death took place from phthisis in any of the private asylums. The statistics afford no information as to the total number of post-mortem examinations performed, but a perusal of the notes of the Commissioners on the various asylums leads to the belief that the number is capable of being increased. At the same time, it is only right to state that original pathological research seems to be carried on with assiduity in many institutions. 180 patients effected their escape; with the exception of 20 all were brought back within the statutory period of twenty-eight days; indeed, 93 were absent less than twenty-four hours. There were 100 accidents, of which 18 terminated fatally, including 12 suicides. Of the 6 fatal accidents not due to suicide 4 were caused by suffocation in bed during a fit, 1 by assault of a fellow-patient, and 1 probably occurred during a struggle with an attendant. This matter was fully investigated by the Crown authorities and by the Commissioners; the attendant implicated was apprehended, but the charge against him was eventually abandoned. The management of the various establishments is favourably spoken of by the Commissioners in the reports of their visits. Overcrowding seems to be rife in the majority of the royal and district asylums, and in these institutions, with one exception, the use of restraint and seclusion is more or less in vogue, although always applied for adequate reasons.

The Commissioners continue to express unabated confidence

Digitized by Google

in the system of boarding out suitable cases in private dwellings, and the beneficial effects of this method are set forth in glowing terms in the lucid and instructive reports of the Deputy Commissioners. As the result of their inspections the Deputy Commissioners are agreed that the condition of those so boarded out is generally satisfactory, and that their environment is conducive to their well-being, both mental and bodily, except perhaps in some instances where the patients are living singly with relatives, whose mistaken kindness frequently leads to the further deterioration of the lunatic. Under the circumstances it is somewhat disappointing to find that the number of pauper lunatics boarded out in private dwellings has decreased during the year 1896 from 2700 to 2667. The authorities, however, do not attach any special significance to this decrease, but attribute it to certain restrictions adopted by them to meet the growing tendency of accommodating more than 2 patients in one house and to prevent the aggregation of lunatics in certain localities. It is not anticipated that these restrictions will have more than a temporary influence upon the number of patients provided for in private dwellings.

The report contains a powerful appeal on behalf of the poorer class of private patients who are only able to pay a very moderate rate of board. The accommodation for this class is at present very inadequate, and the majority have no option but to have recourse to the parish council, who usually consent to their removal to asylums as paupers on the understanding that the whole board, or as much of it as possible, shall be refunded to the parish. The relatives, however, speedily realise that the patient is completely pauperised by this proceeding and frequently endeavour to escape from the burden of maintaining him. The Commissioners, therefore, consider that fresh legislation on the subject is desirable, both in the interests of private patients of the poorer class and the ratepayers, and they recommend that district boards should be empowered to provide accommodation suitable for this class. The proportion of private lunatics in establishments was 46 per 100,000 of the population, which is the same as last year. The ratio of pauper lunatics in establishments per 100,000 of population was at the beginning of this year 224, which is 8 above last year, and is the highest figure yet recorded. The proportion of all pauper lunatics per 100,000 of population shows an almost continuous increase since 1858, and at the beginning of the present year attained its highest point, 287, as compared with the next highest, 281, which was attained last year. The Commissioners, however, are of opinion that the increasing number of registered lunatics does not prove that there is any increased liability to insanity in the community. In this they are in agreement with their *confrères* in England and Ireland. It is a comforting assurance, and it is to be hoped in the national interest that in the long run it will prove correct. The report yields in no particular to its predecessors, and is characteristic of the practical and enlightened policy which has always marked the administration of Scotch lunacy affairs.

OPENING OF THE LONDON MEDICAL SCHOOLS.

WINTER SESSION, 1897-98.

St. George's Hospital.—The opening of the winter session was inaugurated by a pleasant and successful dinner held on Oct. 1st in the Whitehall rooms of the Hôtel Métropole, under the presidency of Dr. T. Whipham, who has recently taken the melancholy step upwards from senior physician to consulting physician. There were over one hundred guests present, and the speeches were all of a cheerful character, as the progress of the school has recently been very great. The best speeches were made by Mr. Holmes, whose connexion with the hospital as honorary treasurer is rather a remarkable sequel to his long connexion with the hospital as surgeon, and by Dr. Isambard Owen, who was able to announce that the respectable number of upwards of fifty students had joined. A hearty vote of thanks was accorded to Mr. G. R. Turner and Dr. Dakin for their services in arranging the dinner. Dr. Manson's introductory address has already been published in our columns.

St. Mary's Hospital Medical School.—The annual dinner of the past and present students took place at the King's Hall of the Holborn Restaurant on Oct. 1st, Mr. A. J. Pepper being in the chair. The dinner was well attended, upwards of 160 persons being present. The chairman was supported by Sir William Broadbent, Mr. George P. Field (the dean of the medical school), Mr. Edmund Owen, Dr. Lees, Mr. Herbert Page, Dr. Luff (sub-dean), and other members of the hospital staff. Among those present were Fleet-Surgeon Preston, R.N., Brigade-Surgeon-Lieutenant-Colonel Myers, Surgeon-Lieutenant-Colonel A. F. Clarke, Dr. John Anderson, C.I.E., Mr. Thomas Wakley, junior, Dr. Waller, Mr. Plimmer, Dr. Laurie, Dr. Danford Thomas, Dr. Nix, Dr. Cundell, Dr. Wills, Mr. B. Thornton, and Dr. John Moore. The toasts of "The Queen" and "The Prince and Princess of Wales" were given from the chair and received with enthusiasm. The chairman proposed "The Army, Navy, and Reserve Forces," which was responded to by Fleet-Surgeon Preston for the Navy, Brigade-Surgeon-Lieutenant-Colonel Myers for the Army, and Brigade Surgeon-Lieutenant-Colonel Danford Thomas for the Reserve Forces. In proposing "Prosperity to St. Mary's Hospital Medical School," the chairman alluded to the great progress made by the medical school during the last fifteen years and to the important positions to which its old students had attained in every branch of the profession. He referred to the successive improvements which the medical school had undergone, and more particularly to the extensive alterations now approaching completion. He contrasted the facilities which now existed for the teaching of physiology with those of former days, and cited as evidences of progress the increased opportunities recently provided for experimental work and laboratory teaching in pathology, including bacteriology, as well as in physiology and chemistry. Dr. Lees proposed the health of the Dean of the Medical School, Mr. G. P. Field responding. The toast of the "Past and Present Students" was proposed by Mr. G. P. Field and responded to by Mr. H. Manders for the past and Mr. W. H. Willcox for the present students. Dr. J. P. Wills proposed "The Staff." Dr. Sidney Phillips replied, and gave the health of the chairman, to which Mr. Pepper responded. A musical programme, arranged by Dr. Scanes Spicer, concluded the proceedings, and the dinner was in all respects one of the most successful of recent years.

Guy's Hospital.—The session opened on Oct. 4th with a house dinner of the Students' Club in the College dining-hall, and a general meeting of the Students' Physical Society in the new lecture theatre. Sir Samuel Wilks was the guest of the Students' Club, and he subsequently presided over the meeting of the Physical Society. More than three hundred past and present students assembled and accorded a hearty welcome to the chairman on his first official visit to the hospital since he had received the honour of a baronetcy. Sir Samuel Wilks welcomed the students who had that day entered the hospital and recounted many amusing reminiscences of the medical school with which he had been connected for more than fifty-five years. He created great merriment among his audience by his criticism of modern "scientific" prescriptions, and pointed out that while so little real progress had been made in therapeutics the profession was making rapid advances in pathology and sanitary science. Dr. Muspratt read a paper to the Society dealing with some of the difficulties—professional, ethical, and legal—to be met with in private practice. At the termination of the meeting the company adjourned to the new physiological laboratories and class-rooms, where an exhibition was held of physiological apparatus, surgical instruments, pathological drawings, &c.

King's College.—On the afternoon of Oct. 1st, the Principal, the Rev. Dr. Robertson, distributed the prizes to the successful candidates, and he delivered an interesting inaugural address. In the evening the customary annual dinner of old students of King's College Hospital was held at Limmer's Hotel, Conduit-street, the chair being taken by Mr. F. Richardson Cross, of Clifton, whose popularity was demonstrated by the numbers attending the dinner, many of whom came very great distances at considerable personal inconvenience. In proposing the toast of the evening, "King's College Hospital and its Medical School," Mr. Cross gave a brief but interesting account of the history of the foundation of University College and of King's College, and dwelt upon the special aims of the founders of King's College, and the impossibility of materially altering these aims unless by appealing for a new charter. He made

Digitized by Google

kindly reference to the long connexion of Richard Partridge with the College and hospital, and in an endeavour to compare the work of Fergusson and of Lister he found a happy simile in the title of Erichsen's Text-book of Surgery. "The Science and Art." Art was represented by Fergusson, science by Lister. The work of Kelly, Baxter, Sir George Johnson, Sir Alfred Garrod, Sir William Bowman, Dr. Todd, Dr. Beale, Dr. Rutherford, and Dr. Ferrier, were in turn dwelt upon in felicitous terms. The Rev. Dr. Wace and the Rev. Dr. Robertson replied on behalf of the Hospital and the Medical School.

London Hospital.—The session was opened by the annual old students' dinner on Oct. 1st. Dr. A. E. Sansom presided over a successful gathering of old students and distinguished visitors, amongst whom were Professor Clifford Allbutt and Dr. John Lowe. The speeches were purposely made as few as possible in order that the foregathering of old friends in the museum might be early indulged in. Dr. Sansom proposed "The Hospital and College" in very felicitous terms. The House Governor made an excellent speech in replying for the hospital, and Mr. Treves responded for the college in his usual admirable style of after-dinner oratory. Professor Allbutt, in replying to the toast of "The Visitors," expressed the great pleasure that he felt in visiting the hospital where so many of his pupils completed their clinical studies, and he trusted that the present cordial relations between the London Hospital and the university which he represented might long continue. The Hospital Photographic Society took a most successful picture of the company by flash light.

Royal Free Hospital and the London School of Medicine for Women.—On Oct. 1st a conversazione was held at the Royal Free Hospital to inaugurate the winter session. Moore Ward, which was temporarily empty, was utilised, having been prettily decorated for the occasion. In addition to a selection of vocal and instrumental music an address, an abstract of which will be found in THE LANCET of last week, was delivered by Mr. J. Grosvenor Mackinlay, the senior ophthalmic surgeon to the Hospital.

University College Hospital.—The winter session was opened at University College Hospital on Oct. 4th, by a lecture delivered at the college by Mr. Raymond Johnson, assistant surgeon to the hospital. The address will be found in another column. In the evening the past and present students of the Faculty of Medicine dined together in the Victoria Room of the Hôtel Cecil, Dr. Charlton Bastian, F.R.S., being in the chair. After the usual toast of "The Queen" the chairman proposed "Success to University College," and mentioned that, owing to the liberality of Sir Blundell Maple, the re-building of the hospital had already commenced, and that it was hoped that the north-west pavilion would be ready for occupation by this time next year. During dinner Dr. F. T. Roberts, Dr. Tait, and Mr. Turner contributed to the enjoyment of the evening by singing several songs, which were enthusiastically received. Among those present may be mentioned Sir William Gowers, Sir John Williams, Dr. Hare, Mr. A. E. Barker, and Mr. R. J. Godlee, the Dean of the Faculty of Medicine.

Westminster Hospital.—The winter session of the medical school opened with an inaugural address by Professor G. B. Howes, F.R.S., and the distribution of prizes by Mrs. Howes. After the address a conversazione was held, which was attended by a large number of old and present students and their friends, a very pleasant evening being passed. No dinner was held this year, but the conversazione attracted a much larger number of old students than usually attended the annual dinner.

St. Thomas's Hospital.—On Oct. 2nd, after the annual distribution of prizes in the Governor's Hall at the Hospital, the old students dined together at the Whitehall Rooms of the Hôtel Métropole. Sir William MacCormac., Bart., took the chair, and the gathering was a most successful one, the number present (181) being an increase of nearly forty over any previous occasion. Dr. Fairbairn, who had given away the prizes in the afternoon, proposed "St. Thomas's Hospital, Past and Present," in a witty speech. This was responded to by the Treasurer, by Dr. Hawkins (the Dean), and by Dr. Foord Caiger. The Dean, in noting the chief improvements of the past year, mentioned the now nearly completed clinical laboratory. He also congratulated the school on having obtained nine acres of the best ground in London for the use of the amalgamated athletic clubs. He spoke in regretful terms of the retirement of Dr. Ord who, in addition to proposing "The Chairman," made a feeling speech in response to an enthusiastic impromptu call. Sir Felix Semon was also congratulated on his recent honour. The chairman on rising to respond to his health met with a great reception and the toast list was completed with the "Honorary Secretaries" proposed by Dr. Barry Blacker.

Middlesex Hospital.—The annual dinner of the past and present students took place on Monday, the 4th inst. Mr. Storer Bennett, F.R.C.S., dental surgeon to the hospital, took the chair. There was a very large gathering, the company numbering upwards of 150, including Lord Strathcona and Mount Royal, Sir Arthur Watson, Bart., deputy-chairman of the weekly board of the hospital, Dr. Buller, of Montreal, Mr. Wilhelm Ganz, Mr. T. W. Nunn, Mr. Balding, of Royston, and all the members of the medical and surgical staff. The toast list comprised the usual loyal toasts, followed by that of "The Services," given by the chairman and responded to by Surgeon-Lieutenant-Colonel G. S. Griffiths, Surgeon E. D. J. O'Malley, R.N., and Captain Wm. Duncan. The chairman next gave the toast of "The Middlesex Hospital and School" in an eloquent speech, in which he referred to the establishment of the Clacton Convalescent Home, the building of the new cancer wing of the hospital, and the extensive additions and alterations now being made to the school buildings. The toast was responded to by Sir Arthur Watson and Dr. W. Pasteur, the dean of the medical school. Dr. Cayley gave the toast of "The Past and Present Students," which was replied to by Mr. J. Smith Turner and by Mr. H. F. Hine, the Broderip Scholar of the present year. The toast of 'The Guests" was proposed by Mr. Henry Morris and acknowledged by Lord Strathcona and Mount Royal and Mr. W. Ganz. Sir R. Douglas-Powell, Bart., proposed "The Chairman," which closed the proceedings which had been of a most enthusiastic and enjoyable description. The musical arrangements were under the admirable guidance of Mr. W. Ganz, who in his speech referred to the fact that he had been present at these annual gatherings for a period of nearly thirty years, the vocal part of the entertainment being rendered by Miss Stella Maris, Mr. James A. Bovett, and Mr. J. W. Myler, whilst Mr. Paul Storving gave two excellent selections on the violin.

THE FRONTIER RISING AND INDIAN POLICY.

WE have, in addition to the war news from the front, reports of the speeches of Sir George White, the Commander-in-Chief in India, and those of Mr. John Morley in this country on Indian policy. With the political aspect of the question regarding the border tribes on the north-west frontier we are not concerned; it is not within our province as medical journalists to discuss questions of military policy. We cannot avoid, of course, forming some opinion thereon in common with any other interested reader of the news from our great Eastern dependency, but our views in this respect can have no special interest for our readers. The future policy of the Indian Government with regard to the tribes occupying the extensive belt of territory between India and Afghanistan is without doubt a very grave question as far as that Government and its exchequer are concerned, and it will most probably form the subject of serious debate when Parliament meets. The present is no time, however, for discussing questions of this kind or for criticising the wisdom or otherwise of the "forward" policy. It is not a time for arguing, but for action. The campaign that has been entered upon must be fought out spite of the cost in life and still more in money that it entails. This country cannot "back out" of the situation without a loss of prestige, which, where Eastern races are concerned, would be little short of disastrous, for it would be great incitement to further action on the part of the aggressive and turbulent tribes on the one hand, and a grave impairment of the moral strength of our own army on the other. The tribesmen must be read a severe lesson and taught that they cannot treacherously raise a revolt against our power with impunity. When that matter has been unmistakably settled will be the time for debating about

Digitized by Google

questions of policy. One of the most surprising and curious things about these frontier risings is the fact that they were totally unexpected. The political officers of the Indian Government were entirely ignorant of what was going on beyond the frontier, the tribes were in our pay for keeping the mountain passes open at the time of their rising against us, there had been no outward and visible sign of their discontent beforehand or at the moment, much less of the widespread nature of the rising and the more or less general inter-tribal organisation that existed. As far as the Afridis were concerned they had been unusually quiet for some time, receiving their retaining pay from the Indian Government and amicably fulfilling their obligations. The fact that this was so shows the necessity where Asiatic tribes are concerned for our being always on the alert. Matters had gone beyond the power of the "politicals" to settle when the exact nature of the situation was disclosed, and it only remained for the sword to cut the knots in it. This has in a great measure been already done. The rapidity, all things considered, of the military movements, the gallantry and success of the troops in the field, and the loyalty and devotion displayed by the native army have been striking features in all that has taken place. A good deal has been made of the hard fighting and apparent checks that have arisen in connexion with General Jeffreys' force, whereas the explanation has simply been that an unexpected and disproportionate amount of difficulty and fighting has fallen to the share of this brigade, which has from the first found itself in several tight places. But it is only fair to say that the General has always been equal to the occasion, and in the expressed opinion of General Sir Bindon Blood has handled his force with great dexterity and skill. General Elles's column and the other brigades have all done extremely well; they have seemingly had less difficulties and, on the whole, less hard fighting to encounter. The wounded are reported to be going on satisfactorily and the troops in the field are enjoying good health. The field hospital system is working well considering the difficulties of the country, of transport, and commissariat it has had to encounter. It may be fairly said that the Mohmand campaign has been a successful one, regard being had to all the trying circumstances attending it in the way of heat, pressure of work, scarcity of water, and the severity of the opposition. The hardship encountered on expeditions of this nature is really very considerable, and the difficulties have, in the opinion of those best able to judge, been admirably surmounted. One of the measures adopted in this campaign—namely, that of disarming the recalcitrant tribes—is a very wise one, for the tribesmen will always be ready to use any arms in their possession. Everything has by this time been pretty well arranged for Sir William Lockhart's punitive expedition to Tirah, and if all goes well with it, as we have every reason to hope and believe, the submission and disarming of the Afridi and Arakzai tribes will before long be secured. The force gathering on the north-west frontier in point of numbers and quality is the finest that has appeared there; it includes the pick of the army, European and native. The number of native followers and of mule and camel transport is enormous, and the expense of the expedition must be enormous also.

ST. MARY'S HOSPITAL, which has been closed for two months for extensive repairs, has now been re-opened for the reception of in-patients. The out-patients' department resumed work on Oct. 4th.—At the Medical School the following scholarships have been awarded:—Entrance Scholarships in Natural Science (September, 1897): £144, M. F. Kelly; £78 15*s*., J. B. Albury; £78 15*s*., D. E. Finlay; and £52 10*s*., J. H Wells. University Entrance Scholarships: £57 15*s*., F. C. Eve; and £57 15*s*., C. Killick.

DERBY ROYAL INFIRMARY CONVALESCENT HOME.—The Holbrook Convalescent Home, which receives cases from the Derby Royal Infirmary, is about to be pulled down and replaced by a larger building which will provide accommodation for twenty-eight inmates. The front of the new edifice will be two storeys in height, the corridors and staircases will be fireproof, and there will be a central tower for the storage of a supply of water. The divisions allotted to each sex will be completely separated. The cost of building is estimated at £5000 or upwards, the whole of which will be defrayed by Alderman Herbert Strutt, J.P., who has also provided an additional sum of £3000 as an endowment.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances of Wribbenhall, by Dr. THEODORE THOMSON.—Wribbenhall is a village of 1278 inhabitants in the rural district of Kidderminster; its ordinary death-rate slightly exceeds that for rural England; but of 218 deaths registered in ten years, no fewer than 54 took place in children under one year of age; the rate of infant death per cent. of registered births being distinctly excessive. Having regard to this, Dr. Thomson describes the sanitary circumstances of the village in much detail, and he gives a number of specific instances of the existing state of affairs. Amongst the latter we find a record of dwellings that are damp and are built back to back, of ill-paved yards, of leaky cesspools close to houses, of offensive cesspit privies, of lack of scavenging even where the closets are of reasonable construction, of wells sunk in the same porous sandstone as that which receives privy and cesspool soakage; and, in short, of most of those conditions which go to make village life even more risky than that of some of our largest communities; and, when it is remembered that infant life is perhaps the most sensitive test of unhealthy conditions of dwellings and their more immediate surroundings, it is not surprising that there is an excess of infant death in this village. Prominent amongst the sanitary needs of the place are a water-supply that shall not be subject to pollution, a decent system of sewerage, a proper system of closets and of excrement disposal, the paving of yards with such an impervious paving as shall prevent soakage of liquid refuse into the soil about houses, and the closure or improvement of houses which are unfit for habitation. Now that these matters have been distinctly set out for the Kidderminster Rural District Council it is to be hoped that some systematic action will be inaugurated.

On the Sanitary Circumstances of Eaton Bray, by Dr. S. W. WHEATON.—This report deals with a Bedfordshire parish of 1330 persons, lying in the newly constituted rural district of Eaton Bray. As regards dwelling accommodation, it seems clear that under the previous sanitary administration a substantial beginning of good work had been done; but there still remains plenty to do to remedy or close houses that are unfit for human habitation by reason of dampness of floors and foundations, bad drainage, and stagnant pools of water or farmyard drainage about them. Then, again, wells are very commonly sunk in such positions as make them liable to contamination from surface washings, from manure deposits, and by reason of leakage from vault privies; and it seems clear that extension of the system under which wholesome water has already been in part procured through the action of the district council is much needed. There is no system of sewerage, and, as must almost necessarily result, nuisance from accumulations of liquid filth arises. Pail privies are replacing vault privies, but the scavenging is imperfectly done. At the same time, it is due to the district council to explain that, whilst they undertake the emptying of pail privies through their contractor, they decline to do the same for vault privies because they thus desire to induce the replacement of the vault privy system by the much more cleanly and wholesome system of pails. Reviewing the whole circumstances of this village it becomes especially clear that until the district council provide a wholesome water-supply for all the inhabitants, and lay down some means of drainage that shall properly dispose of the liquid filth of the place they will not have performed their statutory duty.

On the General Sanitary Circumstances of the Borough of Bewdley, by Dr. THEODORE THOMSON.—This inquiry was instituted on a representation made by the Worcestershire County Council as to the failure of the Town Council of Bewdley to provide a proper water-supply for the borough, to put in force the Housing of the Working Classes Act, and to provide the borough with efficient sewers and thus prevent the pollution of the Severn by the discharge of sewage into it. It would appear to be the custom of the Local Government Board to hand these representations in the first instance to their Medical Department, and in a large number of cases

Digitized by Google

this has done away with the need for further and more formal action, the authorities concerned having acted on the advice given them to remedy the conditions complained of. Bewdley is one of the old and little boroughs of England, and it is diminishing even further in population, the number of inhabitants having fallen from 3088 in 1881 to 2876 in 1891. It thus compares rather with rural than with urban districts, and as such its annual death-rate of 17·3 per 1000 is by no means small. The infantile death-rate is distinctly in excess of that for England and Wales. The cause of this is not far to seek. In certain parts of the town the yard surfaces are broken and uneven, and the dwellings are old, badly lighted, dilapidated, and damp. Indeed, of the dwellings inspected, Dr. Thomson says: "There were few that did not present some defective condition." The existing barrel sewers have their bricks set in mortar. They are of excessive size, and naturally they have become defective and contain silted-up and offensive material; besides which they have no manholes or lampholes, and they are for the most part unprovided with means of ventilation. Some houses are undrained; here and there cobble channels allow of stagnation of slop-water, and the house drains are seldom properly disconnected from the sewers. The cesspit privy prevails generally in the district, and it is contrived on precisely those conditions which ensure nuisance and danger to health and, above all, to infant life. The Town Council contract to empty these structures, but they allow the contractor to make a charge on the tenants. This duplicate system is one that not only always fails, but it is probably quite illegal under the Public Health Act. Drinking-water is scanty at certain seasons in some parts of Bewdley and it is equally defective there in point of quality. "All wells ....., whether public or private, are sunk into formations necessarily largely fouled by excremental and other refuse matters from leaking cesspits, ashpits, sewers, and drains with which the ground under the town of Bewdley is riddled." Dr. Thomson discusses the whole question of the local sanitary administration in detail, and he shows in a convincing manner how unfortunate that administration has been. These small dwindling boroughs are often in default because their responsibilities are beyond their means and their power of action; and it is quite possible that this may be the reason for the persistent neglect of this Town Council to give effect to the advice of their medical officer of health. We are only astonished that the County Council limited their representation to the three matters specified; but we assume they deemed them the most pressing. Now that the maintained neglect in so many matters has been definitely set out, and now that it has been shown that some of the commonest causes of the excessive infant death-rate in this steadily diminishing population are in full operation, it is to be hoped that the County Council and the Local Government Board will follow out the initial step which has been taken in the matter.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

St. Pancras District.—The St. Pancras Vestry have, Dr. John Sykes reports, sanctioned the bacteriological examination of secretion from doubtful cases of diphtheria and of blood from cases suspected to be enteric fever. Every medical practitioner in the district has had an outfit box sent to him, which, when the occasion requires, is remitted charged to the medical officer of health, an uncharged box being at once sent him in return. The charged boxes are transmitted daily to the British Institute of Preventive Medicine, and next day the result is forwarded through the health department to the medical practitioner. Sleeping accommodation has now been added to the St. Pancras "Shelter," in order that persons whose houses are being disinfected and the walls stripped and cleansed may remain in comfort during the whole process. While dealing with the subject of washhouses, and the difficulties pertaining to their provision on an adequate scale, Dr. Sykes expresses the opinion that (1) "in every tenement house there should be required to be provided a place where the occupants can do their clothes washing and personal cleansing"; and (2) that "as St. Pancras contains such a very large number of one- and two-roomed dwellings the by-laws for tenemented houses should be supplemented by a by-law requiring the provision of accommodation for clothes washing and personal cleansing." Dr. Sykes gives a complete list of bakehouses in St. Pancras, and he has constructed an ingenious diagram showing the number of bakehouses above or below the ground. Of the two hundred bakehouses in the parish only 15 per cent. have the floor above the ground level, while 74 5 per cent. have the floor 6 feet or more below the level of the ground.

Islington District.—According to the first quinquennial census the population of Islington on the night of March 29th, 1896, was 336,764. This population gives to Islington a very prominent position as compared with that of most of the thirty-three large towns, the only towns besides London possessing a population in excess of that of Islington being Birmingham, Liverpool, Manchester, Leeds, and Sheffield. It is not customary to think of the parishes of the metropolis in this manner, and hence to some extent their individuality appears to be lost sight of. The density of the population of Islington is greater than that of any of the thirty-three large towns, but there are seventeen sanitary districts in London having densities of population greater than Islington. There were 288 deaths in Islington from measles during 1896, and there seems to have been some want of harmony between the sanitary authority and the London School Board. Mr. Harris points out that if there is to be anything like satisfactory joint action between medical officers of health and the medical officers of School Boards it will be necessary that the *locus standi* of the latter officers shall be defined by the Local Government Board. Medical officers of health have very definite powers with respect to school closure, &c., and although it is eminently desirable that complete harmony should obtain between these officers and the School Board medical officers it appears to us that anything like dual control might at any time prove a source of friction and a danger to the public health. Voluntary coöperation let there be by all means, and let the usual courtesies of interchange of information and opinion always obtain, but decisive action should rest with one officer alone. Mr. Harris, after referring to a case of small-pox which was erroneously diagnosed as chicken-pox, urges that the General Medical Council should compel all students to examine a certain number of cases of small-pox before proceeding to their examinations. However desirable this restriction may be, we are afraid there would be found serious difficulties in the way of carrying it into effect, and although in the future small-pox may be more prevalent than it is at the present time we doubt the expediency of making the proposed restrictions in anticipation. To afford every facility and encouragement to students and medical men to see cases of small-pox when they occur is, it seems to us, as far as matters can go at present. With infectious diseases other than small-pox the case is different, but at the same time we would not withhold a diploma because the applicant for it had not seen a patient suffering from typhus fever. We note that the work of Miss Gray, the female inspector of workshops in Islington, has been attended with good results.

Glamorganshire County District.—Glamorganshire is by far the most important county in Wales, whether regard be had to its area, its population, or its trade; and it is as it should be that the county is setting an excellent example to other Welsh counties, and not a few English ones, in the matter of its public health administration. Dr. William Williams, the county medical officer of health, has made himself thoroughly familiar, by means of a personal survey, with the condition of the administrative county, and he is now turning his knowledge with much effect to the bettering of its sanitary state. Aberdare, with a population of 44,000, is now the only district in the administrative county outside the provisions of the Compulsory Notification Act, and it is to be hoped that before the next report reaches us the district will have tired of its unique position. Glamorganshire has a high birth-rate, both the urban and rural rates being considerably in excess of that for England and Wales. The county death-rate was but 17 per 1000, the separate rates varying from 20 3 and 9 9, while the infantile mortality amounted to 180 per 1000 births. Dr. Williams notes with much satisfaction that the incidence of, and mortality from, enteric fever has diminished. As regards isolation hospital accommodation much has been done during 1896, and we read of a small-pox hospital at Bridgend and of another at Pontypridd, while the sanitary authorities of Cardiff and Barry have erected on the Flat Holm island in the Bristol Channel a joint hospital for the reception of cases of cholera and bubonic plague. What an excellent situation for a hospital for small-pox if suitable sea ambulance provision were obtainable. The progressive people of Barry have, we are glad to see, decided to build a permanent hospital. There are good prospects of further progress during the present year, and there is probability that soon all the districts of

Digitized by Google

the county will be provided with accommodation. Dr. Williams devotes some space to an effort to obtain better regard for the provisions of the dairies, cowsheds, and milkshops order in the county, and he points out that by the improvement of the health of cows the food supply of infants will also improve, and a reduction in infantile mortality may be affected. The condition of the slaughter-houses in the county has much improved of late, a fact for which Dr. Williams can vouch as the result of having visited every such building in the county. Dr. Williams speaks highly of the good effects which have accrued from the visits of inspectors of the Local Government Board. He states that during the last four years from twelve to fourteen authorities have been reported to Whitehall by the county council, and that when government inspectors were sent down beneficial results always followed.

Cardiff Urban District.—The Registrar-General's estimate of the population of Cardiff in the middle of 1896 at 162,690 is, Dr. Edward Walford considers, probably too low, as the usual basis of estimation has been rendered somewhat unreliable by the rapid growth of Cardiff within recent years. Forty-eight cases of small-pox were brought to the notice of Dr. Walford during 1896, thirty-one of the cases occurring in January and February. In a special report upon the subject it is pointed out that among those attacked (*a*) there was no vaccinated child under ten years, (*b*) the only child attacked under ten years was unvaccinated, (*c*) no revaccinated adults were attacked. Dr. Walford points out to his sanitary authority the lesson to be learned from a study of small-pox and vaccination, and we are glad to hear that the Cardiff guardians did their duty as to vaccination. In an interesting and special report upon meat inspection Dr. Walford reminds the council that Cardiff is in quite an exceptional position as regards facilities for such an inspection, inasmuch as it possesses two public abattoirs, and has, through a private Act of Parliament, closed all the private slaughter-houses. Dr. Walford refers to the report of the Royal Commission on Tuberculosis, and insists upon the necessity for proper inspection. He suggests that a veterinary inspector should inspect all the carcasses and meat in the public meat markets, and should submit to him a written report upon any meat which he considers diseased. The medical officer of health would then, if necessary, visit the abattoir and decide upon the necessary steps to be taken. The veterinary inspector should also visit all the cows in the registered cowsheds and perform the tuberculin test upon them, every demonstrated or suspected case of tubercle to be referred to the medical officer of health. Dr. Walford is to be congratulated upon his report being acted upon by the Council and the necessary veterinary inspector being appointed. As far as we are aware the Cardiff Town Council is the first sanitary authority in the United Kingdom which has ventured to propose to apply the tuberculin test to the cows in the cowsheds, and we shall watch the development of the situation with much interest. Dr. Walford also furnishes a special report upon sewer-ventilation: he has obtained returns from several large towns on the methods of sewer ventilation and as to the existence of any illness supposed to be due to the ventilation or non-ventilation of sewers. As a result of his investigations he has been unable to detect "any influence either for good or evil upon the inhabitants of any particular method of sewer ventilation.

Renfrew County District.—Dr. Campbell Munro, when treating of isolation hospital provision in his annual report, asks if it is wise to exceed the original estimate in building such a hospital. In the case of one of the Renfrew hospitals the original estimate was £6000, but the actual cost was £11,500, and Dr. Munro observes that if the actual cost of the hospital had been known in the first instance the hospital would not have been erected and the Joint Hospitals Board would not have been formed. Nevertheless, in this instance there appears to have been no extravagance, and under-estimation seems to have been the only fault. We have known hospitals where similar circumstances have obtained—i.e., where the estimates, owing to the architect's inexperience of such buildings, has been largely exceeded, but where, had the ultimate cost been furnished in the first instance, the hospital would not perhaps have been erected for another ten years. If it is desired to avoid these under-estimates, it is most important to engage an architect who has had previous experience of such buildings, and of their fitting up. The cost of bedding, &c., is often altogether omitted from the original estimates.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6294 births and 3538 deaths were registered during the week ending Oct. 2nd. The annual rate of mortality in these towns, which had declined in the seven preceding weeks from 29·5 to 17·1 per 1000. further fell last week to 16·8. In London the rate was 15·3 per 1000, while it averaged 17·8 in the thirty-two provincial towns. The lowest death-rates in these towns were 11·7 in Cardiff, 12·0 in Croydon and in Halifax, 12·7 in Blackburn, and 12·9 in Portsmouth; the highest rates were 21·5 in Wolverhampton, 21·6 in Newcastle-upon-Tyne, 23·1 in Preston, and 23·7 in Liverpool. The 3538 deaths in these towns included 514 which were referred to the principal zymotic diseases, against 722 and 608 in the two preceding weeks; of these, 229 resulted from diarrhœa, 67 from diphtheria, 61 from "fever" (principally enteric), 60 from measles, 51 from scarlet fever, and 46 from whooping-cough. No death from any of these diseases was recorded last week in Swansea; in the other towns they caused the lowest death-rates in Brighton, Plymouth, and Halifax; and the highest rates in Norwich, Burnley, Preston, and Wolverhampton. The greatest mortality from measles occurred in Preston and in Burnley; from whooping-cough in Derby; from "fever" in Norwich and Burnley; and from diarrhœa in Wolverhampton, Salford, Burnley, Bradford, and Preston. The mortality from scarlet fever showed no marked excess in any of the large towns. The 67 deaths from diphtheria included 49 in London, 4 in Leicester, 4 in West Ham, and 3 in Cardiff. No fatal case of small-pox was registered last week in any of the thirty-three towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital on Saturday last, the 2nd inst., was 3677, against 3579, 3653, and 3697 at the end of the three preceding weeks; 349 new cases were admitted during the week, against 376 and 358 in the two preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 113 and 165 in the two preceding weeks, further rose last week to 167, but were 37 below the corrected average. The causes of 58, or 1·7 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Nottingham, Leeds, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Plymouth, Liverpool, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·4 and 17·8 per 1000 in the two preceding weeks, rose again to 19·4 during the week ending Oct. 2nd, and exceeded by 2·6 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·2 in Perth and 17·3 in Aberdeen to 22·8 in Greenock and 25·2 in Dundee. The 579 deaths in these towns included 41 which were referred to diarrhœa, 18 to whooping-cough, 7 to "fever," 5 to scarlet fever, 4 to diphtheria, and 3 to measles. In all, 78 deaths resulted from these principal zymotic diseases, against 101 and 78 in the two preceding weeks. These 78 deaths were equal to an annual rate of 2·6 per 1000, which was slightly above the mean rate last week from the same diseases in the thirty-three large English towns. The 41 fatal cases of diarrhœa showed a slight increase upon the number recorded in the preceding week, and included 14 in Glasgow, 12 in Dundee, and 7 in Edinburgh. The deaths from whooping-cough, which had increased from 15 to 20 in the three preceding weeks, declined again to 18 last week, of which 9 occurred in Glasgow and 3 in Leith. The deaths referred to different forms of "fever," which had been 9 in each of the two preceding weeks, declined to 7 last week, of which 5 were registered in Glasgow. The 5 fatal cases of scarlet fever were within 1 of the number recorded in the preceding week, and included 2 in Glasgow and 2 in Edinburgh. Of the 4 deaths from diphtheria 2 occurred in Edinburgh, and the 3 fatal cases of measles included 2 in Glasgow. The deaths

Digitized by Google

referred to diseases of the respiratory organs in these towns, which had been 96 in each of the two preceding weeks, rose to 137 last week, and exceeded by 92 the number in the corresponding period of last year. The causes of 33, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased from 22·4 to 28·3 per 1000 in the three preceding weeks, declined again to 26·5 during the week ending Oct. 2nd. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city has averaged 24·0 per 1000, the rate during the same period being 19·4 in London and 18·4 in Edinburgh. The 178 deaths registered in Dublin during the week under notice showed a decline of 12 from the number in the preceding week, and included 20 which were referred to the principal zymotic diseases, against 28 and 39 in the two preceding weeks; of these, 8 resulted from diarrhœa, 6 from "fever," 3 from diphtheria, 2 from scarlet fever, and 1 from whooping-cough. These 20 deaths were equal to an annual rate of 3 9 per 1000, the zymotic death-rate during the same period being 2·1 in London and 2·1 in Edinburgh. The fatal cases of diarrhœa, which had been 13 and 21 in the two preceding weeks, declined to 8 last week. The deaths referred to different forms of "fever," which had been 6 and 9 in the two preceding weeks, declined again to 6 last week. The mortality from diphtheria exceeded that recorded in the preceding week, while the deaths from scarlet fever and from whooping-cough showed a decline. The 178 deaths in Dublin last week included 47 of infants under one year of age and 44 of persons aged upwards of sixty years; the deaths of infants showed a slight decline, while those of elderly persons exceeded the number recorded in any recent week. Five inquest cases and 4 deaths from violence were registered; and 54, or nearly a third, of the deaths occurred in public institutions. The causes of 15, or more than 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT J. McD. MCCARTHY is appointed to the Staff of the Royal Victoria Hospital, Netley, for duty, and is posted to the Medical Division. Surgeon-Lieutenant Cummins is appointed for duty to the Cork District, and Surgeon-Lieutenants Poe and Jephson have been transferred for duty to the Curragh. Surgeon-Major Maturin will hold himself in readiness to embark for service in India shortly. Surgeon-Major Smythe and Surgeon-Captain Tatham have embarked in the transport *Avoca*. Surgeon-Lieutenant W. A. Ward is warned to be ready to embark for India in December.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Lieutenant Clemesha (Bengal) are replaced at the disposal of the Military Department. The services of the under-mentioned officers are placed temporarily at the disposal of the Government of Bombay for employment on plague duty:—Surgeon-Captain Collins, A.M.S., Surgeon-Lieutenant Morgan, A.M.S., Surgeon-Lieutenant Howell, A.M.S., Surgeon-Lieutenant Baines, and Surgeon-Lieutenant Sealy. The services of Surgeon-Lieutenant Robertson (Bengal) are replaced temporarily at the disposal of the Government of Bombay for employment on plague duty. The services of Surgeon-Lieutenant Watling (Bengal) are replaced at the disposal of the Military Department. The services of the under-mentioned officers are placed temporarily at the disposal of the Military Department:—Surgeon-Major Money-Shewan (Bengal), Surgeon-Captain Woodwright (Bengal), Surgeon-Captain Close, (Bengal), Surgeon-Captain Crawford (Bengal), Surgeon-Captain Jordan (Bengal), Surgeon-Captain O'Kinealy (Bengal), Surgeon-Captain H. St. John Fraser (Madras), Surgeon-Captain Fink (Bengal), Surgeon-Captain Hare (Bengal), Surgeon-Captain Wilkinson (Bengal), Surgeon-Captain Hunter (Bengal), Surgeon-Captain Dawson (Bengal), Surgeon-Captain Westropp White (Bengal), Surgeon-Captain Chatterton (Bengal), Surgeon-Captain Davidson (Bengal), Surgeon-Lieutenant Bensley (Bengal), Surgeon-Lieutenant Stevenson (Bengal), Surgeon-Major Deane, A.M.S., Surgeon-Captain Rivers, A.M.S., Surgeon-Captain Fleury, A.M.S., and Surgeon-Lieutenant Knapton (Bombay).

VOLUNTEER CORPS.

Royal Engineers: 1st Durham: Surgeon-Major W. Mearns, M.D., to be Surgeon-Major.

ARMY MEDICAL SCHOOL, NETLEY.

The seventy-fifth Session of the Army Medical School, Netley, commenced on Oct. 2nd. The following is a list, in their order of merit, of the Surgeons on probation who have joined at Netley:—

ARMY MEDICAL STAFF.

H. O. B. Browne-Mason	J. D. G. Macpherson
B. Watts	W. P. Gwynn
H. G. Martin	C. J. O'Gorman
F. S. Penny	M. M. Lowsley
S. de C. O'Grady	N. H. Ross
J. G. Berne	E. A. Bourke
A. H. O. Young	A. C. Lupton
J. E. S. Old	P. H. Collingwood
F. F. Carroll	G. B. Carter

INDIAN MEDICAL SERVICE.

T. H. Delany	G. Tate
J. W. F. Raitt	P. K. Chitale
S. R. Douglas	G. MacPherson
S. Hunt	F. D. S. Fayrer
E. J. O'Meara	W. H. Cox
R. T. Baird	de V. Condon
A. T. Gage	H. A. J. Gidney
G. C. Laing	A. G. Sargent
H. Kirkpatrick	W. Lethbridge

CHOLERA.

The Anglo-Indian papers report that a serious outbreak of cholera has occurred in the wing of the Shropshire regiment at Sitapur; twenty-nine deaths are stated to have taken place in two days. There have been no cases in the Dorset regiment since Aug. 24th, and the report that the corps is still suffering from cholera is incorrect. The latest accounts from Bombay show that the disease is declining in that city and it is hoped that it will soon disappear altogether.

THE RISING OF THE FRONTIER TRIBES ON THE NORTH-WEST.

The papers received from India by the last mail are naturally full of the tribal rising on the north-west frontier and give detailed descriptions of the fighting up to the date of publication, but the telegraphic intelligence received in this country has for the most part anticipated their news.

We hear that Surgeon-Major D. Semple, M.D., Assistant Professor of Pathology in the Army Medical School, Netley, has proceeded on short leave to Maidstone to offer typhoid vaccine and explain the method of vaccination against typhoid fever.

AT a meeting of the British Laryngological, Rhinological, and Otological Association on July 16th the following officers were elected for the ensuing year:—President: Dr. Dundas Grant. Vice-Presidents: Mr. F. Marsh, Mr. G. C. Wilkin, Dr. J. Davison. Council: Dr. W. Milligan, Dr. A. B. Kelly, Mr. V. H. Wyatt Wingrave, Dr. W. Hill, Mr. P. Jakins, Dr. H. Woods, and Mr. Richard Lake. Hon. treasurer: Dr. MacNeil Whistler. Hon. secretaries: Mr. St. George Reid and Dr. F. Potter.

PAUPERISM IN THE NEWPORT (MON.) UNION.—At the meeting of the Newport Board of Guardians, held on Sept. 25th, Mr. Bircham, the Local Government Board Inspector, stated that ten years ago the Newport Union spent £14,000 on in-door and out-door relief, now the expenditure was £21,000, an increase of 33 per cent. The population had not increased at the same rate, and the rateable value had only increased 12 per cent. In 1887 there were 2562 paupers in the union, now they had 3400, an increase of 25 per cent. Mr. Bircham also said that the union was understaffed with relieving officers; a relieving officer could not properly look after more than 200 or 300 cases, but in the Newport Union some of these officers had over 500. The cost per head of each pauper in 1887 was £4 18*s*., now it was £5 9*s*. Mr. Bircham thought that these matters would justify the guardians' very serious attention to these figures, as strict administration was a real kindness and would foster thrift amongst the poorer classes.

"Audi alteram partem."

"THE ELECTION OF A DIRECT REPRESENTATIVE ON THE GENERAL MEDICAL COUNCIL."

To the Editors of THE LANCET.

SIRS,—Although I am very sensible of the kind expressions you have employed in regard to my candidature in the above-named election, I am sure you will permit me to correct an unintentional error in your description of my work. You say in a leading article in THE LANCET of Oct. 2nd that "on one or two occasions he has allowed himself to make unwarranted charges against the President of the General Medical Council which offended not only the President but the Council." I presume that you are referring to a report issued by a committee of the Council to the effect that the President was not as I had shown at the annual meeting of the British Medical Association last year responsible for the execution of certain arbitrary and, as I considered, dangerous by-laws. When that report was issued I at once published with Dr. Bateman in the *Times* and in your columns the extracts from the by-laws which proved that the President and no other official was responsible in the matters named. To this day no one has ventured to challenge our statements made in correction of the finding of the committee. The expression "unwarranted" I feel therefore is not so correct a judgment as your criticism of my other failings which you justly allude to and of which I am very conscious myself.

I am, Sirs, yours sincerely,

Cavendish-square, W., Oct. 4th, 1897. VICTOR HORSLEY.

DANGER TO THE EYES DURING ELECTRIC WELDING, BORING, AND OTHER ENGINEERING OPERATIONS.

To the Editors of THE LANCET.

SIRS,—I have read with very great interest Surgeon Robert Hill's account of the two cases of Electric Light Blindness occurring on H.M.S. *Mars*, published in THE LANCET of July 24th, 1897.

It may be remembered that some years ago I reported the cases of several engineers staying in Leeds who, after witnessing electric welding operations with their eyes only partially guarded, presented some hours afterwards identically the same symptoms—if more severe—which Surgeon Hill describes. In the case of my patients, also, cocaine "acted like a charm," and the spectacle of splendid examples of humanity writhing on their beds in agony, with their lids tightly closed as compared with their appearance and cheerfulness as they entered my rooms on the morning of the day following bears out most fully what Surgeon Hill reports. The publication of my experience, which at the time was the first of the kind on record, drew a letter from a ship-surgeon—I regret that his name escapes me—in which he recorded two very severe and similar cases, both of which occurred in electricians after attending to the electric search-lights carried on the bows of the great liners as they feel their way "dead slow" through the Suez Canal at night. Every one who has traversed "the Ditch" at night will recollect the enormous power of these electric lights. In the case of one of these electricians the attack was so severe that acute delirium set in for a while almost amounting to mania, necessitating temporary restraint.

In all the cases I have seen the vision became normal within twelve hours or less, though the great pain, photophobia, and spasm of the eyelids really made it impossible to test the vision satisfactorily during the attack. It will be observed that a considerable interval intervenes between the exposure to the electric light and the acute period of the attack. Surgeon Hill's cases agree with those I saw in this respect, though my patients noticed nothing abnormal for some hours afterwards, in fact, the electric weldings were witnessed in Birmingham and it was not until after midnight that I received a summons to see the sufferers at their hotel in Leeds. After this experience I made many inquiries and some experiments to enable me to determine the best form of shield to be held in the hands of the workmen, or glasses to be worn as protectors, whilst engaged in these operations with electricity, and I visited several works in Sheffield for this purpose.

Surgeon Hill states that "dark glasses are now always used by the men so employed" amongst the dockyard hands. I suppose from this he means "dark smoked glasses." I have no experience of the actual intensity of the electric glow in the operation known as electric boring, but it is found by experience in Sheffield that ruby glass shields or spectacles of such a density as to reduce the full light of the sun's disc to the intensity of a single candle-power are required to preserve the workmen's eyes from the effects of large electric welding operations. In view of the ever-increasing application of electricity for welding, boring, and like engineering operations, the reports of such symptoms (which agree in all details with those which I had some time ago the opportunity of observing and reporting) are of the greatest interest and importance, as pointing to the best means for their prevention and, when they unfortunately do occur, their cure.

I am, Sirs, yours faithfully,

H. BENDELACK HEWETSON,
Honorary Ophthalmic and Aural Surgeon, Leeds General Infirmary, etc.

Hanover-square, Leeds, Sept. 29th, 1897.

"REFORM IN THE SPELLING OF THE MEDICAL VOCABULARY."

To the Editors of THE LANCET.

SIRS,—Although in his very interesting allusion to the derivation of the word empyema Dr. Moore is quite correct in stating that this word is never spelt empyæma according to the Greek root from which it springs, this word has been spelt with the diphthong. Empyæma, for example, occurs in Dr. Lauder Brunton's Text-book of Pharmacology, where on page 1093 of the 1885 edition Dr. Moore will find it so written.

I am, Sirs, yours faithfully,

Oct. 4th, 1897. M.R.C.S.

A LADY-HELP.

To the Editors of THE LANCET.

SIRS,—Is it customary for examiners' wives to assist their husbands in their work? The following facts were communicated to me by an eye-witness who travelled north from Manchester on Sept. 29th. In the same carriage was seated an examiner in connexion with a northern college. Producing a bundle of papers he handed half of them to his wife to read and mark, which she did, and these were not subsequently read by the examiner himself. The work was most expeditiously gone through—the whole of the papers having been disposed of by the time the train reached Carlisle. All above a certain percentage were torn up and left under the carriage seat. Probably the lady was more than equal to the task, but it would be interesting to know whether she had been duly appointed as an examiner by the college authorities.—I am, Sirs, yours faithfully,

Oct. 4th, 1897. ENQUIRER.

MIDDLESEX HOSPITAL.—The existing school buildings of the Middlesex Hospital are about to be considerably enlarged and partly reconstructed according to plans prepared by Mr. Keith Young. Part of the buildings on the west face of the hospital garden will be pulled down, but the museum and the large theatre will remain untouched. The new buildings will form a block consisting of two portions set at right angles, one of which will contain on the ground floor a complete chemical department, including lecture theatre, laboratory, and lecturer's private laboratory; the upper floor will be occupied by pathological and bacteriological laboratories. The remaining portion of the new block will have in the basement and on the ground-floor a physical laboratory and a very complete physiological department, whilst the whole of the upper floor, some 120 feet long, will be occupied by the dissecting-room and anatomical classroom. The work has been commenced and the buildings are to be ready for use next year.

THE EPIDEMIC OF TYPHOID FEVER AT MAIDSTONE.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

DURING the recent European cholera epidemic there was a strong tendency to shirk the difficulties of complex investigations by laying all the blame on the water-supply. This had a double advantage; theoretically it simplified the problem and practically it was much easier for the local authorities to deal with their water-supply than to attempt to grapple with the hundred and one other reasons that might be adduced as explaining the prevalence of the epidemic. The very elaborate reports which we published and which were the result of careful investigations conducted in the towns which had most suffered from cholera demonstrated very conclusively that the water-supply was only one of many contributing circumstances that had to be considered. It has also been shown that in the long run a great epidemic is beneficent in the saving of human life. It is only in response to the distress and alarm caused by a virulent scourge of this description that the Governments and local authorities concerned can be stirred to take effective measures and remove those conditions which produce ill-health that have always been present. A permanent cause of preventable disease is more fatal than occasional epidemics. In other words, if an occasional epidemic results in the adoption of such measures as will permanently reduce the death-rate, more lives will be saved in the course of a few years than were lost during the epidemic. These are general considerations, but they have a direct bearing on the epidemic of typhoid fever at Maidstone. On all sides the water-supply has been blamed, and there can be but little doubt that the water was the medium by which the disease was spread. If, however, one rests content with this assertion, what will be the result? The water-supply will be improved and there will be less danger of another epidemic; but this risk will not be altogether removed, and there are other epidemics possible besides those of typhoid fever. It is almost certain that the Farleigh supply, which is now completely cut off, will never be utilised again. The Cossington and Boarley supplies, which are derived from the chalk and at considerable depth, seem to be safe, but can it be said that they are absolutely safe? If pure at the intake, can no accident occur during the course of transmission by which they may become contaminated? Then are there no other means by which typhoid fever and other epidemic diseases may be communicated except by the water-supply? Have not epidemics of typhoid fever been traced to milk-supplies? Does it not seem evident that the securing of a pure water-supply only constitutes a part of the task that has to be accomplished? What is more particularly needed, not only with regard to typhoid fever, but with respect to all other preventable diseases, is the removal of all those causes which predispose the population to epidemic disease. It is not only a question of how the pathogenic germs were distributed among the population, but, above all, it is desirable to ascertain why the population was so remarkably susceptible to their influence.

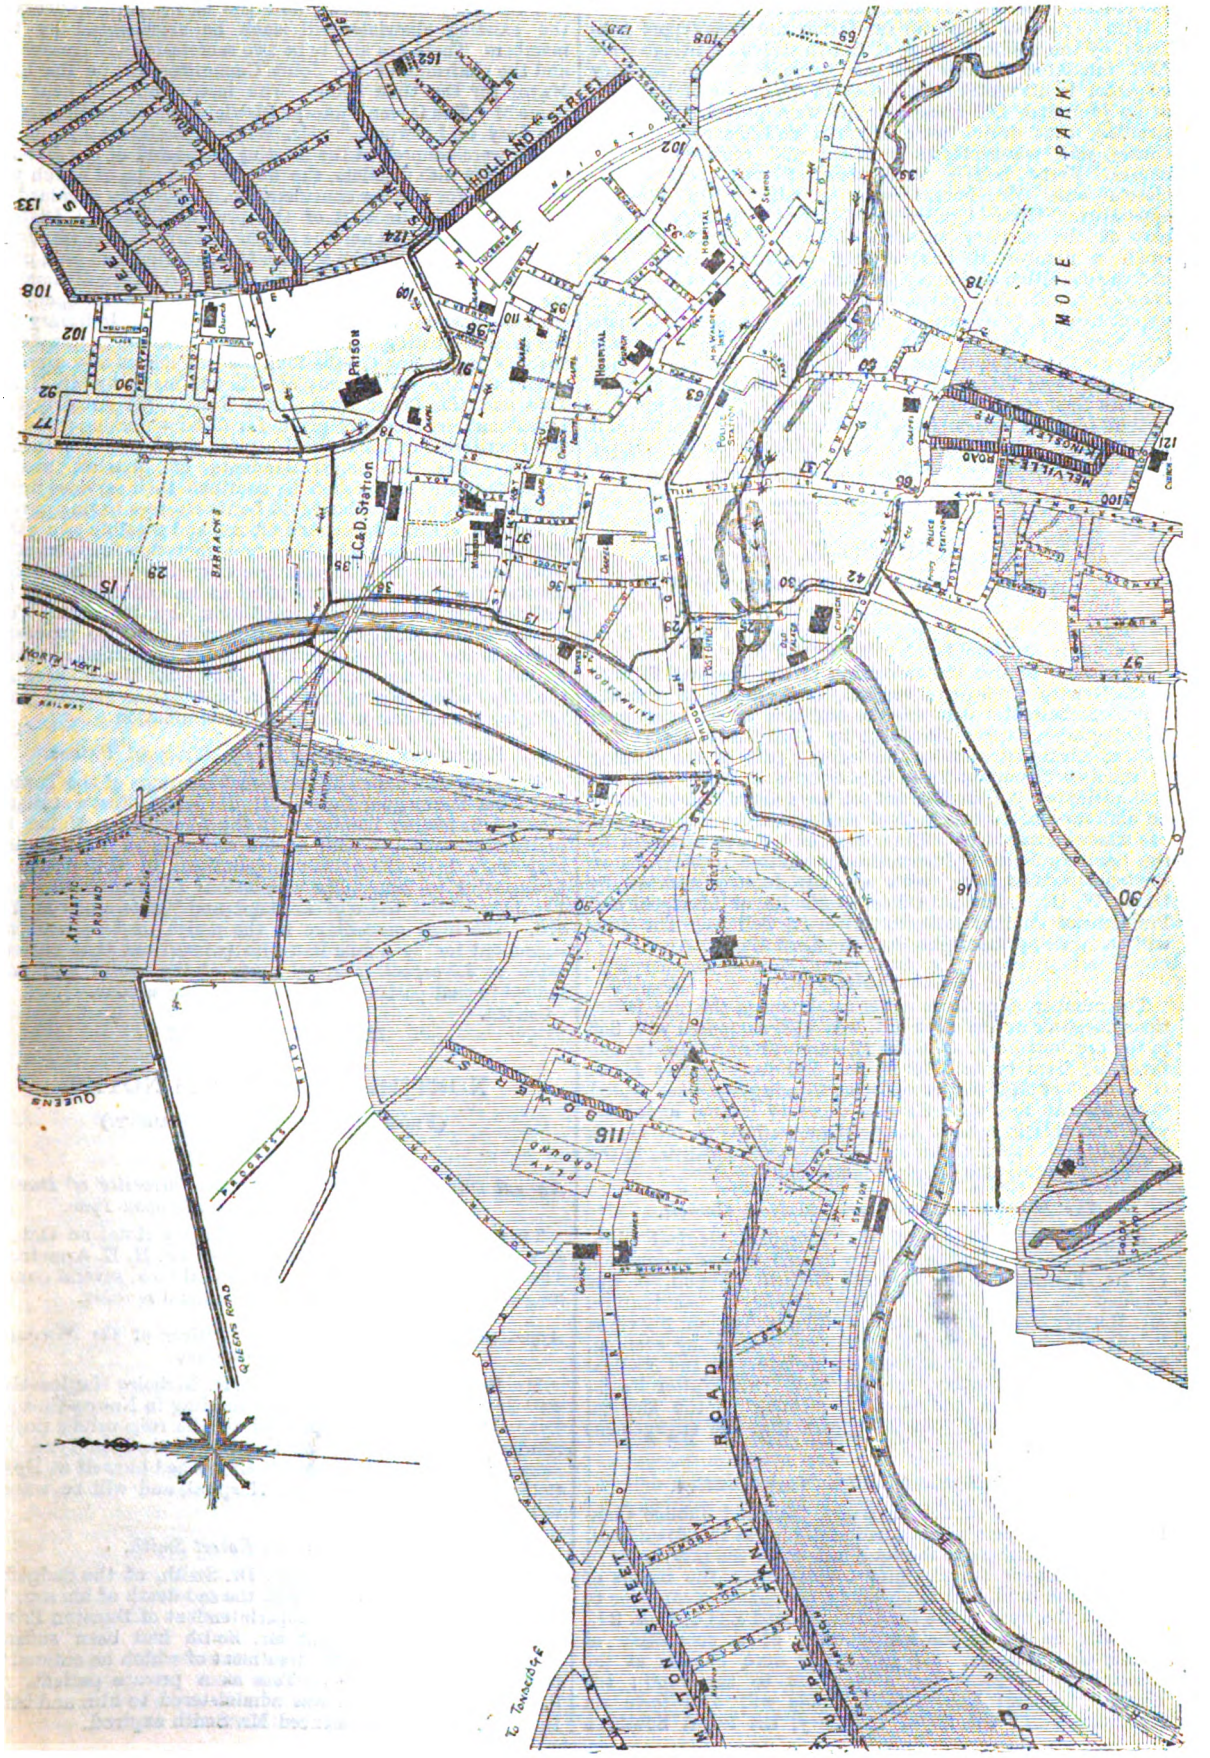
Taking the first fortnight of the epidemic, that is, up to the morning of Oct. 1st, it was found that in the western district of Maidstone there had been 509 cases of typhoid fever notified. In the north-eastern district there were 417, and in the south-eastern district 147. All these three districts received the Farleigh water-supply. In the central district, which received the chalk water from the Boarley and Cossington intakes, there had only been 35 cases. These figures have been taken to prove that the Farleigh supply was the sole cause of the epidemic. But the question arises whether, after all, these figures do not prove too much. It might be urged with at least some show of reason that if the Farleigh water-supply was the sole cause there ought to have been more cases in the central district. If the district spared had not been the central district, but had been situated at some distance from the infected area, and its inhabitants had little or no intercourse with that area, then the argument would have held good. But this is not the case. Maidstone is only a very small town. Even when starting from the most distant points from five to ten minutes' walk suffices to bring one out of the central district and into one of the three districts where the Farleigh water is drunk. There is probably not a single inhabitant of the central district who has not relatives, friends, or business connexions living in one or more of the districts that depend on the Farleigh water-supply. Not scores but hundreds of inhabitants of the central district must have consumed in one form or another water outside their own little district; that is to say, they must have taken some of the Farleigh water, and this at the time when it was contaminated, yet there were only 35 cases of typhoid fever in the central district, as opposed to 1073 cases in the surrounding districts. Again, it may be asked, is not this proving too much? Unfortunately, it has been so far utterly impossible to ascertain the population of the respective districts. The only official figures available divide the town into two instead of four districts. There is the western side of the Medway, which has 16,383 inhabitants; this district—with the exception of two or three streets near the river and on a low level—is supplied exclusively from the Farleigh springs, and it is here that there had been up to Oct. 1st 509 cases. Then there is the eastern side of the Medway, with a population of 17,172. This eastern side comprises the central district with its 35 cases, and the north and south-eastern districts with 564 cases between them. What is the population of the central district? No one knows, and in the confusion and the stress of work caused by the epidemic it is not possible to obtain a computation from the authorities. The proportionate consumption of water would not throw any light on the subject because the employment of water for industrial purposes would render a comparison worthless. Nor can we judge of the population by the size of the respective areas, for though the map shows that the north and south-eastern areas are small they are more densely populated than many parts of the central area; in fact, they are the residential quarters, whereas in the centre many houses are merely business premises. But the eastern and northern sides of the central district are composed of residential streets, and off King-street there are some of the worst slums of the town. Even if only the smaller half or a third of the 17,172 persons who live on the east side of the Medway reside in the central district, it is nevertheless most remarkable that there should have been but 35 cases of typhoid fever. It does seem as if the inhabitants of this locality were less susceptible, and therefore it is necessary to inquire in what respect their condition of existence differs from the rest of the population.

The accompanying map, which with the very courteous and obliging aid of the borough surveyor I was able to draw for this purpose, clearly indicates that there is a marked difference in the local conditions. Figures dotted here and there represent the altitude of the ground in feet. With the aid of these figures it has been possible to divide the town into three zones. That nearest to the watercourses does not exceed at its highest points 40 feet. This, the lowest zone, is indicated in the centre of the map by horizontal lines. A considerable portion of the soil is composed of clay. The next zone, indicated in the map by a light stipple (cf. the area of Mote Park), marks the districts where the levels vary from 40 feet to 100 feet. All the districts beyond these two zones are above 100 feet in altitude, and it will at once be seen that it is in these high districts that the epidemic prevails. The parts of the map shaded with vertical lines represent the three districts that received the Farleigh water-supply. In two places the stippled zone overlaps these vertical lines. It will at once be obvious that the epidemic, which is confined to these Farleigh water-supply districts, is also confined to the high level districts. In the north-eastern district the 417 cases are considerably above the 100 foot limit drawn in the map. The south-eastern district with its 147 cases comes down lower, but only in one or two corners does it go one or two feet below 80 feet. On the other side of the river, in the western district, there is a more considerable overlapping; the Farleigh water-supply here descends to the 40-foot level; but the distribution of the 509 cases has not followed the water-supply and is mainly confined to the higher regions. Indeed, it is a fact on which too much emphasis cannot be laid that the epidemic was not only limited to those districts supplied with the Farleigh water, but that the greater number of cases occurred in the higher parts of those districts which are already in themselves higher than the rest of the town. This was especially remarkable at the

Digitized by Google

commencement of the epidemic. In the map those streets which have been more particularly afflicted—that is, where the greatest number of cases have occurred, as, for example, Milton-street and Holland-street—have been heavily shaded, and it will be seen that they are in the higher parts of the elevated portion of the town. The arrows in the map show the directions in which the sewage flows, and the dark lines show the main or collecting sewers.

Thus a second characteristic fact is demonstrated—namely, that the epidemic does not coincide only with the distribution of the Farleigh water-supply, but it also coincides with the higher latitudes. Though it is generally considered more healthy to live on high ground the reverse has been the case with regard to the present epidemic. That this should be so is not altogether unusual. For instance, in Paris a great deal of typhoid fever has been noted in such high districts as Belleville, Montmartre, and Les Batignolles, while the low-lying quarters nearer to the Seine were comparatively free from the disease. The theory then propounded was that the sewer air travelled upwards and that a greater volume of sewer air forced its way into the houses draining into the upper extremities of the sewers. Might not this also account for the fact that at Maidstone the epidemic is confined almost exclusively to the highest parts of the town? It must be confessed, however, that though topographically this seemed plausible, the manner in which the sewers are built and laid does not tend to confirm this theory. First of all, the great majority of the sewers are pipe-sewers—that is to say, very small. Where there is, as is usually the case in Paris, a very large sewer and proportionately very little water, the downward flow of the water does not prevent the upward current of the air. On the other hand, if the sewer is very small, consisting of a pipe a third or half full of water, the friction caused by the downward rush of the water attracts the air, which then follows the flow of the water and would go down instead of upwards. But, on the other hand, the discharge of sewage is irregular, and though the air might travel downwards in the morning when the pipe sewers are very full of sewage, this would scarcely be the case at night when the pipes are nearly empty. The sewer air, undisturbed by the friction of the rushing water, would travel upwards at night and seek an exit when it approached the top or highest part of the sewers. Here the greater atmospheric pressure coming up from below would force its way through obstacles such as badly constructed traps which it had been unable to penetrate lower down the hill where the pressure was not so strong. Now it is precisely at night that sewer air produces the most deadly effect, for there is less ventilation in the houses and the power of resistance of the sleeper is probably not so great as that of a person who is awake and active. When to this is added the fact that it is acknowledged that the domestic drainage of Maidstone is far from being in a good condition, and that there are many closets which as yet are unprovided with any flushing apparatus, it seems quite clear that there are favouring circumstances to weaken the resistance to typhoid infection, when this is introduced by the medium of a contaminated water-supply.



In mitigation of this argument it must be noted that the general plan of drainage does not altogether favour this theory of the ascension of the sewer air to the higher levels, at least where the central district is concerned. First, it must be noted that the town is cut in two by the Medway. In the map is shown by arrows the direction in which the sewage flows, but the lines drawn only indicate the main collecting sewers. The two principal collecting sewers are on either side and close to the river. They are large sewers with insufficient fall and therefore they are not self-cleansing. They have only been thoroughly cleaned out once, but they are constantly being partially cleaned. The western side of the town, which is shaped like an elbow, is entirely surrounded at its base by its main collector. Towards its northern extremity this collector receives the whole of the sewage from the eastern side of the town. The gases generated on the western side cannot, however, travel over to the eastern side, for the syphon which conducts the sewage from the eastern bank of the Medway right underneath the river bed to the collector on the western bank constitutes a gigantic trap which would effectually arrest the passage of sewer air. It will be noted, however, that at a very short distance beyond this connecting syphon there is a branch main sewer which travels at right angles up Buckland Hill till it reaches the asylum, which is at an altitude of 234 ft. This branch sewer, as it follows an upward course, might well constitute itself into a sort of ventilating shaft for the principal collector, and this just at the point where the two drainage systems join together and the sewage of the en town passes by. It is also to be observed that, though complaints are made in almost all directions of the bad odours escaping from the man-holes or street-sewer ventilators, a man-hole connected with this branch collecting drain, which, as explained above, may act as a ventilating shaft for the principal collector, is considered one of the very worst in the town. The main collector proceeds to a distance of about one and three-quarter miles from the town. Here there are precipitating tanks. The sludge obtained by mixing lime with the sewage is pressed into cakes, but the manure thus made is of such little value that the town authorities instead of selling it have to pay a shilling a ton to get it carted away. The sewage after clarification flows into the tidal part of the Medway. The treatment of the sewage at the outfall can, however, have little or no bearing upon an epidemic which has occurred nearly two miles away up the stream. What is of interest is to trace how far the sewer air from the main collector which runs at the foot of the western district can travel upwards and so permeate the houses above as to render their inhabitants especially susceptible to the germs of typhoid fever.

It would be a strong argument if it could be shown that, on the other hand, in the central district where there have been so few cases of fever no such permeation of sewer air exists. It may be said that this is indeed the case because the houses of the central district are built on lower ground and that there is likely to be a greater escape of sewer air in the higher grounds beyond. But by referring to the map it will be seen that the sewers of the central district have no direct communication with the sewers of the north-eastern infected district and are cut off from the south-eastern infected district by two collecting mains and by the little River Len. The north-eastern district is hedged round by a collector of its own which separates it from the central district—unless, however, some slight connexion is established by means of storm overflows. In any case there is a greater rise from the north-eastern collector to the district it drains than there is from the central collector up to the central part of the town. The same observation may be made for the south-eastern district. Thus it will be seen that the sewers of the three infected districts are more likely to act as ventilators for the main sewers that flow below than the sewers of the central and non-infected district. May not this fact help to account for the extraordinary susceptibility of the inhabitants of the three infected and high districts? May it not likewise explain the immunity which is equally extraordinary and which the inhabitants of the low-lying central district have enjoyed? The fact that these latter have a different water-supply does not, under the circumstances, and as has been already explained, suffice to account for the immunity enjoyed in the central district, as so many of its inhabitants must in their social intercourse have drunk the water of the infected quarters.

Under all these conditions it does seem most essential that the investigations concerning the epidemic should not be limited to the question of the water-supply. It will then be found that, at least in the north-eastern infected district, many houses are jerry built, the domestic drains faulty, and the public sewers defective. The soil being hard, to save time and expense headings were driven through instead of digging trenches. These headways were often not straight, and instead of drilling through rocks the sewers were sometimes conducted over rocks. Under these conditions the sewers were easily blocked, and several have had to be re-laid. Also a part of this north-eastern district is on quarried ground. The hollows have been filled up with quarry rubbish, which if not in itself unhealthy is certainly very unsteady. Consequently, as the sewers do not rest on a firm foundation they are apt to bend and break. The subsoil then gets saturated with sewage, and the gases generated are attracted to the interior of the houses by the higher temperature prevailing within the dwellings. On the western side of the town there are also notable imperfections. Innumerable complaints have been made of the abominable smells emanating from the big sewer which runs down the Queens-road from the asylum and across the northern extremity of the western district. It is this sewer which ultimately reaches the main collector just after it has received the whole of the sewage from the

A MAP OF THE MAIDSTONE EPIDEMIC (*for explanation see page 947.*)

Digitized by Google

eastern side of the town. There is a good fall in this sewer, but probably there is not sufficient water.

With regard to domestic sanitation the last report published by the medical officer of health states that there were 6007 inhabited houses in the borough. The sanitary inspector in his report relates that in the course of last year in no less than 200 houses drains were provided or reconstructed, that drains were repaired and cleansed in 436 houses, and water-closets cleansed and repaired in 300 houses. Forty houses were provided with new water-closets and 346 houses were supplied with flushing apparatus. These figures show laudable activity on the part of the sanitary authorities, but as applying to so small a number of houses they likewise indicate how bad the condition of domestic drainage must have been. It is notorious also that any number of houses still remain in urgent need of the sanitary inspector's visit, and that there has been the very greatest difficulty in compelling some landlords to put the drains of their houses in order. With all these facts before them it would seem like an attempt to shirk their responsibilities and to avoid the performance of their obvious duties if the local authorities were to limit their effort in dealing with this epidemic to the simple question of the water-supply.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University College, Liverpool.

THE work of the winter session of the Medical Faculty of University College, Liverpool, commenced on the 4th inst., a feature of which was the omission of the customary introductory address. Profiting by Lord Lister's expected visit to Liverpool to take the leading part in the opening of the new Thompson-Yates Laboratories in May, 1898, the authorities of the medical school have asked him to deliver an address also to the medical students, a request which he has kindly acceded to. The course of lectures arranged by the Sanitary Science Instruction Committee commences on Wednesday, Oct. 6th, with an introductory address by Dr. E. W. Hope, Medical Officer of Health of Liverpool and Professor of Public Health in University College. The chair will be taken by the Right Hon. the Lord Mayor.

Health of Liverpool.

The number of patients under treatment in the city infectious hospitals on the 30th ult. was 412, compared with 358 in the previous week. Of these 17 were suffering from typhus fever, 90 from typhoid fever, and 289 from scarlet fever. Of a total of 276 deaths registered during the week ended Sept. 25th no less than 80 were those of infants under one year, and this in spite of the persistent efforts of the health authorities to instruct parents in the poorer localities in the matter of feeding and hygienic influences.

The Election to the General Medical Council.

At a special meeting of the Liverpool Medical Club, convened to consider the vacancy caused by the resignation of Dr. Rentoul in the General Medical Council, it was decided to support Mr. Victor Horsley's candidature. Mr. Horsley has accepted an invitation to explain his views to the members at the club-rooms on Wednesday evening, Oct. 6th. He is also to address the members of the Medical Institution on Thursday, the 7th inst. Sir Walter Foster was also to have addressed a meeting at the Medical Institution this week, but it appears that the engagement has been cancelled.

Liverpool Diamond Jubilee Commemoration.

The final stage of the Liverpool Diamond Jubilee Commemoration Scheme was enacted yesterday at the Town Hall, when the subscribers to the fund met under the presidency of the Lord Mayor to take into consideration the means of applying the fund, and to appoint a permanent committee to carry out the work. The fund has realised £23,472 19*s.* 2d., and will be under the management of a committee of twenty-six members. Six gentlemen were chosen at the meeting to represent the subscribers to the fund; the Nurses Training School and Home will also have six representatives; the Royal Infirmary, the Royal Southern Hospital, the Northern Hospital, the Hospital Sunday and Saturday Committees, and the lady-superintendents of the existing districts will each be represented by two members. There are also to be two secretaries and treasurers, and the chairman of the Joint Committee will be the Lord Mayor for the time being. The institution will bear the name of "The Queen Victoria District Nursing Institution of the City of Liverpool." Mr. William Rathbone's proposals which were adopted at the meeting, consisted of the division of the city into districts, the number and area of which will be matter for further consideration, though the standard of nursing should be that of the present Liverpool District Nursing Association and the Queen Victoria Jubilee Institute, London. To enable the scheme to be carried out on a comprehensive basis, Mr. Rathbone suggested a plan of amalgamation with the present Nursing Institution and of coöperation with the hospitals. He proposed that the Royal Infirmary and the present Nursing Institution should be asked to transfer to the new institution (1) the four district homes now used by them; (2) the endowment of £10,000 made by Mr. Henry Tate and the Roger Lyon Jones Fund; (3) subscriptions and donations specially given for district nursing; and (4) the contributions from the Hospital Sunday and Saturday Funds. The lady-superintendents of districts are to be at the same time asked to continue their services under the new institution. The David Lewis trustees having agreed to build a central home and offices, and possibly two other district homes if required, the commemoration fund, together with the funds and income transferred from the existing institution should be appropriated as an endowment for the maintenance of the new institution and its work. The Northern and Royal Southern Hospitals are also requested to join in the supply of a certain number of trained nurses to be paid by the new institution. The Lord Mayor eulogised the help he had received from Mr. Rathbone in maturing and bringing the scheme to a successful termination.

Percentages of Lunacy in the Liverpool Unions.

Attention was drawn at the recent meetings of the Toxteth and West Derby guardians to Mr. H. Jenner-Fust's statistics relating to pauper lunatics. In the West Derby Union the proportions were 1 in 332; in the township of Toxteth-park they were 1 in 423 of the population; in the parish of Liverpool 1 in 208. The proportions for Lancashire were 1 in 448; whilst those of England and Wales stood at 1 in 410. The high percentage in the parish of Liverpool was accounted for by a guardian who pointed out that patients came to Liverpool from all parts of the world and were landed in that parish and in the adjoining unions.

Oct. 5th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Annual Dinner of Old Students of the University of Durham College of Medicine at Newcastle-upon-Tyne.

THIS dinner took place at the County Hotel on Oct. 1st at 7 P.M. The chair was occupied by Dr. H. E. Armstrong. There was a good attendance of medical men, several coming long distances to be present at this annual *réunion*.

Appointment of Resident Medical Officer at the Newcastle-upon-Tyne Dispensary.

Mr. W. Hardcastle, the son of Mr. Nicholas Hardcastle, a well-known medical practitioner residing in Newcastle-upon-Tyne, has just been appointed to the responsible post of resident medical officer at the Newcastle-upon-Tyne Dispensary. Mr. W. Hardcastle distinguished himself at Epsom College and at Charing-cross Hospital, and will be warmly welcomed in his new office.

Sad death of Mr. Robert Smith.

Much sympathy is felt with Dr. Smith, of the Sedgefield Asylum, and with his family at the sad death of his son, Mr. Robert Smith, the medical superintendent of Dunston Private Asylum. It appears that Mr. Smith had been suffering from fistula in ano, for the treatment of which he entered the hospital at Stockton-upon-Tees as a private patient. On Sunday last chloroform was administered to him and before the operation was commenced Mr. Smith expired.

PARIS

(FROM OUR OWN CORRESPONDENT.)

Anti-leprous Serum.

AT a recent meeting of the Academy of Medicine M. Hallopeau read a communication upon the treatment of leprosy by hypodermic injections of the serum prepared after the manner of Dr. Carrasquilla. M. Hallopeau's conclusions are not altogether favourable. He points out that the therapeutics of leprosy are in need of much further elucidation, for it is well known that this disease advances by successive exacerbations which are followed by periods often lasting for a considerable time of spontaneous amelioration and retrogression of the disease so marked as to simulate cure. If any drug is given during the time of exacerbation the cessation of acute symptoms which follows is very likely to be attributed to this drug, although the same result would have followed without the intervention of anything at all, and if, on the other hand, treatment is begun during a period of retrogression it is very easy, although quite wrong, to attribute the continuance of the amelioration which follows to the influence of the treatment rather than to the fact that such periods of amelioration almost always follow and continue for some time after an acute stage. A method of treatment which was really curative would be marked by the appearance of the retrogressive stages at shorter intervals, by making these more complete, and by preventing the occurrence of the crises. The anti-leprous serum prepared and reported on by Dr. Carrasquilla does not satisfy these requirements. It is made by injecting horses with serum from the blood obtained by bleeding a leper. To take this point first, there is no proof that this human serum contains the specific leprosy microbe, and, again, the blood not being taken from the horses with strict antiseptic precautions always contains a multitude of organisms unconnected with leprosy. Nevertheless, it is generally well borne and seldom provokes any but slight reactions both local and general. As to its action on leprosy this appears to be but slight, the tubercular manifestations persist even after its use for a long time, and despite the assertions of its introducer it does not prevent new crises appearing. The periods of retrogression which appeared in lepers treated by this method in the hospital of St. Louis did not in any way exceed those which occur spontaneously after a crisis. An anti-leprous serum could more probably be prepared by injecting into some animal the lepra bacillus. It is proposed to continue investigations into the serum therapeutics of leprosy despite the many difficulties which surround the subject, not the least of which is the fact that leprosy cannot be cultivated in animals.

The Action against a Medical Man.

Dr. Laporte has been set at liberty conditionally owing to the persistent representations of the Syndicate of Medical men of the Department of the Seine. The judge has expressed a wish to be supplied with the full report of the experts who consider the matter to be a case of "homicide by imprudence, but attended with hardly any responsibility." The syndicate has given bail for 2000 francs, and Dr. Laporte has gone to stay at the house of his brother-in-law, where he will be out of the way of the reporters, who have on this account become much less sympathetic. The trial will take place in about three weeks. At the commencement of the legal proceedings, which took origin in an information laid by the resident medical officers at the Tenon Hospital, where the patient was taken after the operation by Dr. Laporte and where she died two days later, the committee of the syndicate sent a letter to the President of the Surgical Society and to the President of the Society of Hospital Medical Officers. In this letter, which was couched in very moderate though definite terms, the committee begged the "Chef de Service" to point out to the resident medical officers that in the interest of the profession great prudence was necessary with regard to the terms in which they referred to the treatment adopted by the outside practitioners in the case of patients before their admission to the hospital. The opinion of the resident medical officers was said to be almost always unfair because they ignore the surroundings of the patients previously to admission, and such opinion has the most deplorable effect, not only on the patient, but also on outsiders, for they induce the relatives of the patient to make representations which the magistrates are only too glad to listen to, and the scandal affects the entire profession. All the men in private practice approve of the terms of this letter, which is intended to bring about a remedy for a really crying abuse. On the other hand, a municipal councillor is going to demand that every police station shall provide a case containing all the instruments necessary for operations of urgency, and in particular those which have to do with obstetric operations. The councillor is going to ask for a vote of 25,000 francs. As there are eighty police stations in Paris it is very unlikely that for this sum either enough instruments will be provided or that those which are will be of the best quality.

Anniversary of the Death of Pasteur.

An impressive celebration was held in the Pasteur Institute in the Rue Dutot at 3 P.M. on Oct. 3rd, the occasion being the second anniversary of the death of M. Louis Pasteur. The entire staff of the institute and of the establishment at Garches assembled at the tomb in the crypt of the institute and laid on it a wreath of flowers from the gardens at Garches, where the horses used for the production of anti-toxin serum are stabled. In the morning the Pasteur family, who are at present in the Jura, attended Divine service in the Church of Arbois, the native place of the lamented deceased. M. Duclaux and Dr. Roux, who are also at Arbois, will return to Paris this week, and a meeting of the committee for the Pasteur monument will then be held. The amount on the subscription list, which will thereupon be closed, is at present upwards of 300,000 francs (£12,000).

The late Professor Verneuil.

A bust of Professor Verneuil, provided by those interested in the seaside homes for phthisical patients and executed by M. Salières, was unveiled on Oct. 3rd at La Baule (Loire Inférieure), the small town where Professor Verneuil was born. He was one of the first to recommend the treatment of chronic tuberculosis, and especially of surgical tuberculosis, by removing the patients from the general hospitals, which he rightly considered to be incubators for the cultivation of Koch's bacillus, and dispersing them in special sanatoria near the sea. He was the founder of this system of seaside hospitals, to which it should be mentioned that the medical profession very liberally subscribed, and the whole of the latter part of his career was devoted solely to its organisation. Professor Le Dentu presided at the unveiling of the bust and delivered an admirable address on Professor Verneuil's life and work, the proceedings terminating with a banquet at the Hôpital Mauspha.

Oct. 4th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

A Poet's Advice to Medical Students.

AT a time when so much wise counsel is being given to "the brave young British soul" (as Carlyle called him) on the threshold of nature-study and its application to the healing art it may not be superfluous to add the advice of one of Italy's humanest and strongest poets, whose lyric faculty has won for him the name of the "Italian Heine." Not book-learning, he warns the student, will make a man of him, although it enriches him intellectually. He must interview nature face to face, he must keep in touch with living reality, if he is to act as well as speculate and to leave his personal imprint for good on the contemporary world. The mere "arm-chair scholar," for all his wealth of knowledge and facility of discourse, is but a poor performer when he comes out into the open to give practical effect to what he knows—nowhere poorer or more "ineffectual" (to use Carlyle's favourite word) than in grappling with disease at the bedside. But let us hear Giuseppe Giusti:—

"Bevi lo scibile
Tomo per tomo,
Sarai chiarissimo
Senza esser uomo.
Se in casa eserciti
Soltanto il passo,
Quand' esci sdruccioli
Sul primo sasso.
Dal fare al dire
Oh! v'è che ire:"

(You may drink in the knowable from volume after volume; you will gain the height of celebrity without being a man.

Digitized by Google

If only within doors you try your paces, when you go abroad you stumble over the first stone. Between doing and discoursing there is, oh! such a journey.) Wise words these when the tendency is to "read up" the literature of the subject rather than to "look up" the facts as they are found in nature. "You cannot be too much in the hospital," "you cannot be too familiar with the aspect of disease," were admonitions to the commencing student which Syme and Hughes Bennett (two of the best teachers of the Edinburgh school) were never tired of repeating. "Disease has a language of its own," said another clinician of the same seat of learning; "its expressions, *φωνᾶντα συνετοῖσι*, must be interpreted aright if you are to encounter it on equal terms." So said Thomas Laycock when insisting on the value of that "physiognomic diagnosis" of which the typical master was the "English Hippocrates," Thomas Sydenham. "A great physician" is not only "a great artist," he is also "a great moral force," testing the speculation of the study by the touchstone of the consulting-room and inspiring confidence by his habit of "getting at the root of things." As man of thought and as man of action he fulfils the twofold part described so well by Goethe:—

"Es bildet ein Talent sich in der Stille;
Sich ein Charakter in dem Strom der Welt."

(A talent moulds itself in tranquility; a character in the stream of the world). By no nationality, it may be said with safety, has this ideal combination been exemplified to better purpose than by the British—a fact attested by the more candid, as well as competent, observers of continental Europe; a fact to be remembered and laid to heart by every young aspirant to the medical career in the English-speaking world.

Professor Sanarelli and the Yellow Fever Bacillus.

I hear from Genoa that Professor Sanarelli, director of the Istituto d'Igiene at Montevideo, is shortly expected at that port, whence he will start on a series of visits to our leading medical schools, at each of which he will deliver a lecture on his discovery of the bacillus of yellow fever and set forth his maturer recommendations for its prophylaxis as well as clinical treatment. The recent outbreak of the disease in latitudes hitherto supposed to be proof against its inroads lends a practical interest to this aspect of the subject which is sure to be reflected in the discussions which, I understand, he cordially invites.

The Health of Leo XIII.

The few who on Sunday last were privileged to be present at the mass which His Holiness celebrated in the "Capella Interna" (inner chapel) of his private apartments were struck with the strength of voice and general aspect of health he displayed. In the afternoon of the same day, profiting by the change to genial warmth after the recent fall of temperature, he descended to the Vatican Gardens and enjoyed their unique amenities for about an hour and a half. Since then he has availed himself of the continued fine weather to spend many hours of each day in that delightful retreat, the Palazzina della Torre di Leone IV., already described in THE LANCET.

Oct. 3rd.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

Unveiling of the Pirogof Statue in Moscow.

"To the Memory of Pirogof" is the title of a small pamphlet which has just been published in Moscow under the editorship of Professor Diakonof. This little work contains a complete record of the proceedings in connexion with the erection and unveiling of the statue to the great surgeon which now adorns the space in front of the cliniques in Moscow. The statue was unveiled with considerable ceremony on Aug. 3rd (15th) of the present year. It was originally intended and arranged to perform this function during the week of the International Medical Congress so as to enable foreigners to be present, and it is, perhaps, rather regrettable that this intention was not adhered to. The occasion was an interesting one, and many foreign medical men would have been glad to have the opportunity to assist in doing honour to the greatest of Russian surgeons. Probably it was found impossible to fit this in with the many other arrangements made for the Congress week, and consequently the Sunday preceding the opening of the Congress was selected for the ceremony. The statue is a bronze seated figure of heroic size, on a pedestal of the same material. It was the last great work of the sculptor, Mr. W. Sherwood, a Russian artist and Academician of English descent, whose death within the last few weeks has left a vacancy in the roll of members of the Russian Academy of Arts. Of the ceremony of unveiling the monument and presenting it in permanence to the University of Moscow little need be said. It commenced with a *panikhidi* or memorial service for the dead at the base of the statue, followed by the formal presentation of the statue to, and its acceptance by, the University authorities. A vast number of wreaths were laid on the base of the monument and this completed the first part of the ceremony. The second part was held after a short interval in one of the large theatres of the clinique. The meeting here was under the presidency of Professor Diakonof, who holds the chair of operative surgery in the University of Moscow. In the many laudatory orations which were here spoken in memory of Pirogof, and which now appear in print in the pamphlet just issued, a very full and clear account is contained of the life-work of this unquestionably great surgeon and administrator. It is for his services to the art and craft of surgery that he is probably best known outside Russia. In his own country he is quite as much remembered for what he did in the cause of education during his brief tenure of office under the Ministry of Education and by his powerful writings as for his work as a surgeon. Nor were these the only services he rendered to the cause of progress. Space, however, does not permit of their recapitulation here; and it must suffice to say that, when all allowance is made for the glamour of the occasion upon which the speeches now printed were delivered, and for the rhetorical hyperbole not infrequent on such occasions (to be quite just, the present collection of speeches do not err excessively in this direction), these addresses will remain as a worthy tribute to the memory of a man of whom Russia is rightly proud.

The Effect of Smoking on the Health.

The vice of smoking (if it be a vice) is thought to be rather decreasing in Russia. Certainly there is a very general impression that the number of non-smokers now met with is considerably greater than it was a few years ago, when smoking was practically universal among the so-called upper classes. Dr. Mendelssohn[1] publishes a number of observations which he made a few years ago upon the effect of smoking on the health of students, and the statistics he gives are not without interest. In 1890 a circular form was sent to every student of the Army Medical Academy in St. Petersburg and in the Technological Institute containing a large number of questions which the students were asked to answer, and 1071 replies were received. Among the medical students 54·66 were found to be habitual smokers, and among the technological students only 47·18. Juvenile smoking must be common in Russia if we are to accept the table of returns of the age at which these students began to smoke. Two were returned as beginning the habit at the age of six years, 3 at the age of nine years, 11 at the age of ten years, 5 at the age of eleven years, 27 at the age of twelve years, and so on, the maximum being reached at the age of seventeen years. The average number of cigarettes smoked daily by a medical student was 19·64 and by a technological student 22·88 (Russian cigarettes are more than half paper mouthpiece and therefore much smaller than English cigarettes). But the most interesting figures are those which deal with the effect of smoking on the health. Of the smokers 16·09 per cent. were found to have some affection of the respiratory tract, while only 10·69 per cent. of the non-smokers were so affected. In regard to diseases of the alimentary tract the figures were respectively 11·88 and 9·92 per cent., and of both tracts combined 8·77 and 3·22 per cent. In every case the smokers gave the higher percentage. Turning to the effect of the age at which the habit was begun it was found that those who had acquired the habit before the age of sixteen years gave higher percentages of illness (19·05, 13·09, and 13·69 in the above three groups) than those who began at or after that age (14·77, 11·34, and

[1] The Journal of the Russian National Health Society, September, 1897.

Digitized by Google

6·6 respectively). Another table shows the deleterious effect of inhaling the smoke when smoking; inhalers gave percentages of illness of 16·14, 12·2, and 9 25 respectively, as compared with 15 38, 7 69, and 2·56 among those who did not inhale. Some other tables complete the article, which closes with some *pia desiderata*, more particularly as to the need of instructing the youth of the day in the harmfulness of smoking. There is of course nothing new in the figures or in the conclusion they point to, but they serve to emphasise the long since admitted fact that smoking is to a certain extent a harmful habit, especially in the young.

A Green Cross Society.

In 1891 a movement was set on foot in St. Petersburg for the formation of a society having for its object the organising of "first aid" in case of accidents, and to be called the "Green Cross Society." No practical results, however, followed the suggestion until the present year, when a committee was formed and a constitution of the society was drawn up which only awaits ratification. The need for some such organisation is shown by some statistics collected by M. Chernik, the originator of the movement, from which it appears that in the twelve years 1881–93 there were in St. Petersburg alone 46 618 registered accidents, and that the number is increasing yearly.

Sept. 23rd (Oct. 5th).

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Infectious Disease in Melbourne.

THE health officer of the city of Melbourne (Dr. James Jamieson) has submitted a report on the prevalence of infectious disease in the city since 1891, the year that notification came into operation. The comparisons are made for the first half of each year 1892 to 1897, and include all cases reported, though many on inquiry proved not to have originated in the city. The figures are put into the form of tables showing the number of cases reported in each of the months January to June for six years.

Typhoid Fever.

	1892.	1893.	1894.	1895.	1896.	1897.
January	23	10	21	21	41	27
February	39	29	18	33	39	19
March	40	29	31	25	33	20
April	30	27	24	19	24	8
May	18	23	14	8	17	18
June	11	8	5	7	7	10
Total for six months	161	126	113	113	161	102

Diphtheria.

	1892.	1893.	1894.	1895.	1896.	1897.
January	0	4	4	2	3	10
February	5	0	5	3	10	12
March	4	1	6	12	7	7
April	5	2	4	4	8	10
May	6	3	1	6	10	14
June	6	3	3	4	4	23
Total for six months	26	13	23	31	42	76

Scarlet Fever.

	1892.	1893.	1894.	1895.	1896.	1897.
January	2	5	2	5	3	7
February	5	8	1	1	12	17
March	6	3	5	2	4	24
April	6	6	4	2	1	20
May	10	8	8	5	7	22
June	4	2	3	2	20	19
Total for six months	33	32	23	17	47	109

It will be noted that typhoid fever showed less prevalence in the first half of this year than in any other of the period, and less probably than in any year since records have been kept. Cases of that disease are fairly, if not amply, provided for in the general hospitals. Diphtheria has become steadily more prevalent and fatal since 1893, when it had reached a low level. The epidemic has not attained the dimensions of the great outbreak of 1889–90, but hardly seems yet to have reached its climax. Scarlet fever has also been much more prevalent in 1897 than in any other year of the period, though there is some reason to believe that there will not be any further considerable increase. Happily, the epidemic has been a mild one and the fatality comparatively small. For these two diseases the present hospital accommodation is quite inadequate, the only provision being a few beds at the Melbourne Hospital. Until provision is made more in accordance with the needs of a large city like Melbourne the task of checking outbreaks of these diseases is a hopeless one.

The Queen's Jubilee Hospital for Consumption in New South Wales.

As previously stated, it was decided to establish hospitals for phthisical patients in New South Wales as a permanent memorial of the Queen's reign. Considerable difference of opinion exists, however, as to the character of the hospitals to be provided. Dr. Sydney Jones champions the view that country sanatoria should be first built and a receiving house in Sydney (and a resolution to that effect was carried at a meeting of the profession held on June 11th). Dr. W. C. Wilkinson is the chief upholder of the other view that a special hospital for phthisical patients should be built near the city. At the last meeting of the New South Wales Branch of the British Medical Association the questions were discussed again, and Dr. Wilkinson's proposals were carried. His view is that our observations and treatment of phthisis should be carried out on scientific lines, and a scientific station established where the various forms and stages of the disease can be scientifically discriminated and classified. From this as a base the scheme, in ever-widening circles, as funds were provided, would include other hospitals and homes in the country. The special hospital would afford the most efficient means of prophylaxis by affording the most accommodation for the poor and removing the sources of infection from the homes of the poor. In the early stages also much good could be done in such an institution by the use of tuberculin. He did not deny the value of climatic treatment. It is indispensable in many conditions, especially when streptococcal infections are present; but the idea of cottage homes, however specious at first sight, was impracticable; owing to the great expense entailed relatively few would be benefited by the large outlay, therefore he advocated the erection of a special hospital first and the continuance and enlargement of the present Home for Consumptives at Thirlmere.

A Medical Man Convicted of Administering a Noxious Substance with Illegal Intent.

On Aug. 23rd last a medical practitioner named George Joseph Walsh, of Exhibition-street, Melbourne, was convicted at the Criminal Court of administering a noxious substance to Lucy Jessup with illegal intent. From the evidence of Jessup it appeared that fearing she was pregnant she consulted Walsh, who confirmed her suspicions and gave her some medicine and pills to bring on a miscarriage. Two days afterwards she aborted, and the family physician, Dr. J. H. Williams, was called in, but declined to attend, and told them to communicate with the police. Walsh then saw her and secured the unused medicine. At the trial the defence was a denial of the charge.

Death of Dr. Youl.

One by one the older members of the profession in Australia are passing beyond that bourne whence no traveller returns, and on Aug. 5th died one of the best known men in Melbourne, Dr. Richard Youl, who for forty-four years had filled the post of city coroner. He was of marked personality and his name was a household word to all sections of the community. He was a man of great natural shrewdness, with a keen and often caustic wit. His faculty for discriminating between true and false evidence was remarkable, and his charges to juries were an admixture of humour, cynicism, and quaint philosophy, but were always logical and showed a profound knowledge of human nature. He frequently interlarded the evidence of witnesses with remarkable comments, and his peculiar idiosyncrasies and singularities of thought and utterance made him a striking figure in public life. During his long period of office he held over 12,000 inquests and applied himself enthusiastically to his duties, especially studying the causes that contributed to accidental deaths. He insisted on a post-mortem examination being held in every case, and it is largely due to his exertions that much greater care is now taken to prevent accidents to workmen and that the sanitary condition of the hospitals and similar institutions has been so much improved. It was almost entirely due to his efforts that the Infant Life Protection Act was passed, and it was on his suggestion that the Victorian Infant Asylum was founded. Besides holding the post of coroner Dr. Youl was President of the

Digitized by Google

Medical Board, and was for a long time President of the Board of Health until that body was re constituted. He was also an official visitor to the lunatic asylums and chairman of the Police Medical Board. He remained also in the practice of his profession and was regarded as a very sound physician, though his official duties prevented him from engaging in much practice; but his medical services were always at the disposal of the poor without fee. In private life he was highly esteemed, being a brilliant and witty conversationalist, and though somewhat abrupt and satirical he was at heart extremely kindly and charitable. For many years he was a martyr to gout, so that his life was burdensome, but he worked on with indomitable courage and literally died in harness, having held three inquests only two days before his death, which occurred from heart failure and bronchitis in his seventy-first year. Truly it might be said of him—*Labor vita vitæ est.*

Aug 30th.

Obituary.

CHARLES SMART ROY, M.A. CANTAB., M.D. EDIN., F.R.S.,

PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF CAMBRIDGE.

ALTHOUGH Professor Roy had been in failing health and unable to do any work for the last two years, the sad news of his death at the premature age of forty-three years, which occurred suddenly in an epileptic fit on the evening of Monday, Oct. 4th, will come as a surprise to his past pupils and many friends who only knew that he had been obliged to stand aside from active work. The complete nervous breakdown which culminated two years ago and necessitated his giving up his professional duties and the appointment of a deputy professor, Dr. A. A. Kanthack, had been for some time foreshadowed by attacks of ill-health, and his mental activity had been greatly impaired thereby.

Born in 1854 at Arbroath his early education, begun at St. Andrews, was continued at Edinburgh University, where he took the M.D. degree in 1878 after having held the post of resident physician at the Edinburgh Royal Infirmary in 1875. After this appointment he worked for a time at the Brown Institution on the pathological anatomy of epizootic pleuro-pneumonia. He then acted as surgeon to the Turkish troops in the Servian War, and it is to be feared that his ultimate breakdown and premature death were the indirect result of mental and bodily strain experienced during this campaign. On his return to England he resumed work at the Brown Institution for a time, but soon went to the Continent, and for about a year worked at physiology under the late Professor du Bois Reymond and at pathology under Professor Virchow, in Berlin. During the next year he acted as assistant at the physiological institute of the University of Strassburg and then went to work at Leipzig under Professor Cohnheim, whose influence made itself felt on his future life's work. During this time he had begun publishing a series of papers on the heart, spleen, and kidneys, and demonstrated by means of the oncometer the variations in volume of the two latter organs; in the case of the spleen he pointed out the rhythmic contractions that normally occur, and on the kidneys he studied the effects, as regards the bulk of the organ and the excretion of urine, produced by introducing water, urea, and drugs into the blood of the renal arteries.

In 1880 he was appointed as the first George Henry Lewes student in physiology, and did original work under Professor Michael Foster in Cambridge. After investigating for the Argentine Republic an epidemic which was shown to be anthrax, he was in 1882 appointed Professor Superintendent of the Brown Institution. In 1884, being then thirty years of age, he was elected to the Fellowship of the Royal Society and to the newly made Professorship of Pathology in the University of Cambridge, entering on his duties in October of that year. He became attached to Trinity College, and had rooms in Nevile's-court until his marriage in 1887 to Violet, daughter of the late Sir G. E. Paget, Regius Professor of Physic. Before this he had, together with Dr. C. S. Sherrington, now Holt Professor of Physiology in University College, Liverpool, investigated an outbreak of cholera in Spain.

As a pathologist Dr. Roy devoted himself chiefly to the experimental part of the subject and especially to the investigation of the disturbance of function; pathological physiology, in fact, was the line of research to which, as Cohnheim's pupil and follower, he was most attracted. He was, as has been already seen, a physiologist first and only became a pathologist secondarily, and perhaps as a result the subjects of morbid anatomy and histology hardly received from him the amount of attention and research that would be required from an ordinary teacher of pathology in a hospital school. His aim, however, was to carry on pathology to the same extent and along much the same lines as those on which the sister science physiology had been advanced. There can be no doubt that he was extraordinarily well fitted for this object. In the first place he had a genius for the invention of apparatus for recording graphically the results of experimental research; in connexion with his favourite subject, the vascular system, there are quite a number of instruments for registering the arterial and endocardial pressure, the expansion of the heart and vessels, and so forth which remain as memorials of his ingenuity and inventive power. His powers of mechanical invention and his bias for problems dealing with physical questions can be traced, not only in his own researches, but in those of his pupils and demonstrators. In the second place, he was a skilful and accomplished operator; the rapidity and accuracy with which he made the dissection necessary in experiments on animals were very striking.

As a teacher he appealed rather to the advanced students and to those anxious to do some original work on their own account than to the rank and file of pass men. It was, in fact, one of his ambitions to form around him a school of workers like that which centred around Ludwig, and to have a steady stream of work issuing from his laboratory. Although his earlier years in the professorial chair had been hampered by the facts that adequate laboratories and thoroughly appropriate fittings were not forthcoming until about 1889 and although the later part of his term of office was interrupted by failing health, the list of researches and papers that he directed or in part carried out is a long one. Among his demonstrators are many whose names are well known and who are now holding responsible teaching posts, while the John Lucas Walker students (Hunter, Adami, Kanthack, Lorrain Smith, Westbrook, and Cobbett) worked under his direction. Most of his own work at this time was done conjointly and no mention of it would be complete without a reference to his researches into cardiac mechanics and experimental disturbance of the circulation published in conjunction with Dr. Adami, who for three years acted as his demonstrator and only left Cambridge to take up the chair of pathology at Montreal. Their work on the papillary muscles, on the relation between the heart-beat and the pulse, and on strain as a cause of valvular disease has a most important bearing on the problems of clinical medicine. He originated, planned the outlines, and unselfishly helped his pupils in researches on endocardial pressure, the specific gravity of the blood, the pathology of shock, the production of lymph, and other subjects. Had his health and life been spared he would no doubt have accomplished his desire of bringing out an exhaustive treatise on cardiac physiology and pathology. As a lecturer his matter was excellent, stimulating and suggestive of original thought and work, and dealing largely with experimental physiological pathology, but his delivery was rather indistinct, too rapid, and therefore somewhat difficult to catch. A rather bluff manner and abrupt address were the outward expressions of a thoroughly sterling and generous nature. Strong in his convictions and forcible, if sometimes impetuous, in his acts, Roy was certainly no courtier, but these very properties made him a generous and steadfast friend to those who knew and trusted him.

Mrs. Roy, who devotedly watched over and nursed her husband during a long and terribly anxious period of failing health and illness, has no children to console her in her bereavement. We are informed that Professor Roy's funeral will take place on Friday, Oct. 8th. The service will be held in Trinity College Chapel at 3 P.M. before the interment at Mill-road Cemetery.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Convocation held on Sept. 25th the following degrees and diploma were conferred:—

Doctor in Medicine.—Wilfred Ernest Alderson, M.B., B.S. Durh.; Walter Alexander Atkinson, M.B., B.S. Durh.; Octavius Beven; M.B., B.S. Durh.; Charles Vincent Dingle, M.B., B.S., B.Hy. Durh. Robert Ayton Dunn, M.B., B.S, B.Hy. Durh.; Harry Harte Gourley, M.S. Durh.; Ferdinand Henry Halse-Francis, M.B., B.S. Durh.; Arthur Jervis, M.B., B.S. Durh.; Sodeinde Akisiku Leigh-Sodipe, M.B. *(in absentid)*; Robert Cecil Leonard, M.B. Durh.; Richard Pearson, M.B., B.S. Durh.; Frederick Robson, M.B., B.S. Durh.; and Charles Rawdon Wood, M.A., M.B., B.S., Durh.

Doctor in Medicine (Practitioners of Fifteen Years' Standing)—Thomas Reuell Atkinson, M.R.C.S., L.S.A.; George Booth, M.R.C.S., L.R.C.P.; Charles Donkin, L.R.C.P., L.F.P.S.; Percy Septimus Jakins, M.R.C.S., L.S.A.; Frederick William Jordan, M.R.C.S., L.R.C.P.; Hugh Pugh Rowlands, M.R.C.S., L.R.C.P., L.S.A.; Charles James Vlieland, M.R.C.S., L.S.A.; and Oliver Withers, M.R.C.S., L.R.C.P.

Bachelor in Medicine (M.B.).—Arthur William Aldridge, M.R.C.S., L.R.C.P., Mason College, Birmingham; Walter Osborne Arnold, Grant Arnott, John David Dodds, Joseph Livingstone Frazer-Hurst, Ernest William Gilroy, Percy Holgate, Albert Adam Hope, James William King, Malcolm Gordon McBean, Norman McCall-Smith, and Walter Augustus Peverley, College of Medicine, Newcastle-upon-Tyne; Arthur Riley, M.R.C.S., L.R.C.P., Westminster Hospital; Charles Salkeld, B.A., and Thomas Ovens Scott, M.A., College of Medicine, Newcastle-upon-Tyne; Henry Francis Shea, St. Thomas's Hospital; Gilbert Smith, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Alfred Edward Stevens, St. Thomas's Hospital; John Aston Swindale, Mason College, Birmingham; William Ardendt Hagestadt Waite, Yorkshire College, Leeds; and William Longstaff Wight Walker, College of Medicine, Newcastle-upon-Tyne.

Bachelor in Surgery (B.S.).—Arthur William Aldridge, M.R.C.S. L.R.C.P., Mason College, Birmingham; Walter Osborne Arnold, Grant Arnott, John David Dodds, Joseph Livingstone Frazer-Hurst, Ernest William Gilroy, Percy Holgate, Albert Adam Hope, James William King, Malcolm Gordon McBean, Norman McCall-Smith, and Walter Augustus Peverley, College of Medicine, Newcastle-upon-Tyne; Arthur Riley, M.R.C.S., L.R.C.P., Westminster Hospital; Charles Salkeld, B.A., and Thomas Ovens Scott, M.A., College of Medicine, Newcastle-upon-Tyne; Henry Francis Shea, St. Thomas's Hospital; John Aston Swindale, Mason College, Birmingham; William Ardendt Hagestadt Waite, Yorkshire College, Leeds; and William Longstaff Wight Walker, College of Medicine, Newcastle-upon-Tyne.

Bachelor of Hygiene (B Hy.).—William Edmund Harker, M.D., B.S.

Diploma in Public Health (D.P.H.).—George Clement Belcher, M.R.C.S., L.R.C.P.

PRESENTATIONS TO MEDICAL MEN.—Mr. Richard Adams, L.R.C.P. Edin., M.R.C.S. Eng., Medical Superintendent of the Cornwall County Asylum, at Bodmin, gave on the 24th ult., on his retirement from that office, which he had held over forty years, a farewell evening entertainment in the Great Hall of the Institution. Advantage was taken of the occasion to present Mr. Adams with a valuable silver coffee tray as a testimonial of esteem, subscribed for by 157 of the officials, past and present.—Dr. Jas. Wheatley, medical officer of health of the borough of Blackburn, has been the recipient of a clock and barometer. The testimonial bore the following inscription: "Presented to James Wheatley, Esq., M.D., by the inspectors and officials of the Health Department, on the occasion of his marriage as a small token of respect and esteem."—Mr. Robert Laidlaw, M.B. Edin., of Ladybank, Fife, has been presented by the members of the Ladybank Branch of the St. Andrew Ambulance Association, with a gold albert chain, in recognition of services rendered as their lecturer.—Mr. J. P. Bickersteth, the Deputy-Chairman of the London and North-Western Railway Company, on distributing on the 28th ult. the First Aid certificates of the St. John Ambulance Association to the successful members of the staff in the assistant goods manager's and chief passenger superintendent's offices, pointed out the advantage—in fact, the necessity—of a staff of a railway company being acquainted with ambulance work. This had led the directors recently to bring First Aid prominently before the staff all over the company's system and to provide the means whereby all who wished could obtain a practical knowledge of the work. The present opportunity was embraced to present to their gratuitous instructor, Dr. Ramage, a box of microscopic apparatus as a small token of esteem.—At Pontypridd, on Sept. 30th, Mr. Howard Davies, M.R.C.S. Eng., L.S.A., was presented with a silver-mounted riding whip by the members of the St. John Ambulance class in appreciation of his services as honorary lecturer. Mr. Nathan Raw, M.D. Durh., B.S., was on Saturday last, just before his departure from the Dundee Infirmary for his new sphere of labour in the Mill-road Infirmary, Liverpool, the recipient of a present, subscribed for by the nursing staff of the former institution, which consisted of a pair of silver candlesticks and silver inkstands enclosed in a case. On the outside of the lid of the inkstand are engraved Dr. Raw's initials, and inside is the following inscription: "Presented to Nathan Raw, Esq., M.D., B.S., L.S.Sc., F.R.C.S.E., by the nursing staff of the Dundee Royal Infirmary in grateful remembrance of his unfailing courtesy and consideration. October 2nd, 1897."

THE PLAGUE IN BOMBAY PRESIDENCY.—The accounts from Bombay and from different districts of that Presidency are not by any means so satisfactory as could be desired. The epidemic of bubonic plague has been slowly extending itself and seems to be following, more or less, the course of that which visited Hong-Kong. The disease has not disappeared from Bombay, and is even still more prevalent in Poona, Kirkee, and in the Kolabar, Nasik, Satara, and other districts; hence it is thought that, in addition to the disease indigenous to Bombay, it is probably increased by cases being imported into the city. Moreover, the death-rate from fever and other causes in Bombay continues high.

DIPHTHERIA IN LONDON.—In our issue of Aug. 7th we gave a summary of the data respecting diphtheria prevalence and mortality in London during the four-weekly period ended on July 17th, and showed that the total of 1011 notifications exceeded that for any like period since November last. The average weekly yield of cases in July was 253 against 224 in June; and the registered deaths 135 in number against 137 in June, the per case mortality for the respective months being 13·3 and 15·3 per cent., the smaller total of cases in June having been accompanied by a slight excess of registered mortality. But if the data for the July period were thus excessive, those for August, ended on the 14th, were still less satisfactory, the notifications reaching 1111 and the registered deaths 163. The cases notified yielded a weekly average of 278, and whilst all the sanitary districts of London save one were invaded, 6 of them had each upwards of 50, and an aggregate of 397 notifications, as compared with only 20 notifications in all in other 6 districts. The deaths, 163 (a weekly average of 41), exceeding as they did those of the July period, were, despite a higher total of attacks, sufficiently numerous to increase the per case mortality, which became 14·7 per cent. The next succeeding four-weekly period, ended on Sept. 11th, witnessed a decided fall alike in notified attacks and registered deaths. The notifications were 866, or an average of 216 per week. Three sanitary districts returned no cases, and other 4 had each 50 and upwards, and an aggregate of 246. In 6 districts, however, only 10 cases were notified in all. The registered deaths were 117, or 29 weekly, and the per case mortality was 13·5 per cent, approximating to that of the July period. The deaths in the next succeeding week, ending Sept. 11th, were 35, or 6 above the average of the preceding four weeks; and a still greater rise was witnessed in the week ending Sept. 18th, the deaths registered being 45, although the corrected decennial average for the thirty-eighth week of the years 1887-96 was 44. But apart from the fact that the decennial average for any one week is a very fluctuating and unreliable figure, it must be held in mind that the high total of the week last named is almost identical with that average only by reason of the excessive persistence of the disease in fatal form for many years past, the decennial average thus ever growing as the several weeks of each year continue to show heavy mortality data. Going back ten years we find that the decennial average for the particular week now in question was only 17·2; five years later it had grown to 26·4, and now it is 44·4. Hence the fact that the deaths nowadays in any one week only reach the average has become a false factor in determining the potency of the disease. In the week ended Sept. 18th Paddington and Islington had each 4 deaths, and St. Marylebone, St. George-in-the-East, Whitechapel, and Wandsworth 3 deaths each. The admissions were 167, as compared with 131, 140, and 156 in earlier weeks; and on the Saturday 1021 patients were returned as being in hospital on account of diphtheria. In the Outer Ring there were 12 deaths registered from the

Digitized by Google

disease, 6 being in West Ham, and 3 in Brentford registration districts. Last week's returns show a still further increase in fatality from diphtheria alike in the county and Outer Ring of London.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—The first Broderip Scholarship has been awarded to Mr. H. F. Hine and the second to Mr. G. H. Lucas. The first Entrance Scholarship has been awarded to Mr. Wm. Gillitt and the second to Mr. Rees Phillips.

LONDON HOSPITAL MEDICAL COLLEGE.—The following Entrance Scholarships have been awarded: Price Science Scholarship, £120 Mr. J. Jones; Price Anatomy and Physiology Scholarship, £60, open only to competitors from Oxford or Cambridge, Mr. C. Warren (Oxon.); Science Scholarship, £60. Mr. R. T. Dolbey; science scholarship, £35, Mr. M. T. Williams.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The first Entrance Scholarship in Natural Science (£150) has been awarded to Mr. W. H. Harwood-Yarred, and the second (of the value of £60) to Mr. Francis H. Whitehead. The University Scholarship (of the value of £50) has been awarded to Mr. Frank Cecil Eve, B.A., of Emmanuel College, Cambridge.

AN AGED PHILANTHROPIST.—Mr. George Müller, the founder of the orphan houses at Ashley Down, Bristol, entered upon his ninety-third year on Sept. 27th, and the anniversary was, as usual, marked by a large number of congratulatory messages from friends and former inmates. There are now upwards of 1700 orphans in the homes, with nearly 200 helpers.

CHARING-CROSS HOSPITAL MEDICAL SCHOOL.—The following Entrance Scholarships have been awarded: The Livingstone Scholarship (100 guineas), to Mr. S. A. Boyd; the Huxley Scholarship (55 guineas), to Mr. W. J. O'Brien, and the Universities' Scholarship (60 guineas), to Mr. W. G. Rogers. Entrance Scholarships have also been awarded to Mr. E. Bayley (60 guineas), Mr. C. L. Lakin (40 guineas), and Mr. G. S. Welham (30 guineas).

WATER-SUPPLY OF THE ISLAND OF PORTLAND.—The scheme of water-supply promoted by the local authority of Portland has received the approval of the Local Government Board. It will supply the Government departments, Admiralty, prison, and the inhabitants. The source of the supply is situated in the chalk hills at Upwey, between Weymouth and Dorchester, and the water will be conveyed by pipes to Portland. The work will be commenced immediately.

DUNDEE ROYAL INFIRMARY.—Dr. Nathan Raw, the medical superintendent of Dundee Royal Infirmary, having been appointed superintendent of the Mill-road Infirmary at Liverpool, was entertained at dinner at the Queen's Hotel, Dundee, on Sept. 28th. Lord Provost McGrady presided, and there was a numerous company. The chairman, in proposing Dr. Raw's health, made very complimentary references to his administrative ability, saying that he came to the Dundee Infirmary from Bolton in 1893, and that those who were connected with the institution, especially the directors, regarded the period of over four years which he had spent there as one of the most successful chapters in its history. Dr. Raw, in replying, said that at the time of his appointment he was a complete stranger to Dundee, but he now seemed to know everybody, and would always cherish the recollection of the kindness which had been shown him.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ARMITAGE, E., L.R.C.P., L.R.C.S. Ed., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health by the Grimsby Rural District Council.

BRIERLEY, JAS., has been appointed Analyst for the Borough of Newbury.

CLOTHIER, H., M.D. Lond., L.R.C.P., M.R.C.S., has been re-appointed Medical Officer of Health by the Hornsey Urban District Council.

CORBETT-SINGLETON, F. E., L.R.C.P. & S. Edin., has been appointed Clinical Assistant to Out-patients at the Chelsea Hospital for Women.

CRAN, R. D., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Salford Sanitary District of the Salford Union.

DENT, H. C., M.R.C.S., has been appointed a Medical Officer by the Erpingham Guardians and Council.

FARRAR, J., M.D. St. And., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Gainsborough Sanitary District of the Gainsborough Union.

GRAHAM, D. J., M.B., C.M. Edin., has been appointed Assistant Medical Officer to the City Hospital for Infectious Diseases, Edinburgh.

GRANT, F. W., M.D., B Sc. Edin., has been appointed Medical Officer of Health for Lossiemouth and Branderburgh.

HARRIS-LISTON, T., M.R.C.S., has been appointed Assistant Medical Officer of the Lawn Hospital, Lincoln.

HODGES, G. W. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 2 Sanitary District of the Bridgnorth Union.

HOOTON, W. A., L.R.C.P. Lond., M.R.C.S., L.D.S. Eng., has been appointed Dental Surgeon to the Manchester Royal Infirmary, vice G. W. Smith, resigned.

HOUSLEY, J., M.D. St. And., M.R.C.S., D.P.H. Glasg., has been re-appointed Medical Officer of Health by the Retford Urban District Council.

JACKSON, D. H., M.A., B.Sc., Ph.D., has been appointed Junior Demonstrator in Chemistry at University College, Bristol.

LE PELLEY, AMELIA M., M.B. Lond., has been appointed House Surgeon to the Belgrave Hospital for Children, London, S.W.

MACKAY, H. J., M.D. Edin., has been re-appointed an Honorary Medical Officer for the Devizes Cottage Hospital.

MCCARDIE, W. J., B.A., M.B., B.C. Cantab., has been appointed an Anæsthetist to the General Hospital, Birmingham.

MONTGOMERY, WM. P., M.B., B.S. Lond., F.R.C.S. Eng., L.R.C.P. Lond., has been appointed Resident Surgical Officer to the Manchester Royal Infirmary.

MOULD, P. G., L.R.C.P. Lond., M.R.C.S., has been appointed a Third Assistant Medical Officer to the Cheadle Asylum.

MUSGRAVE, C. B. T., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed a Medical Officer by the Erpingham Guardians and Council.

OLIPHANT, FRANK, M.B. Edin., has been appointed House Surgeon to the Kidderminster Infirmary.

OWEN, ARTHUR DUNLEY, B.Sc., M.R.C.S., L.R.C.P. Lond., has been appointed District Surgeon and Surgeon to the B.S.A. Police at Melsetter, Rhodesia, South Africa.

PAGET, CHAS E., L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed Medical Officer of Health for the County by the Northamptonshire County Council.

PARTRIDGE, S., M.D. Edin., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Darlaston Urban District Council.

PEARSON, H. A., L.R.C.P. Lond., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the No. 5 Sanitary District of the Blandford Union.

PORRITT, ERNEST E., M.B., C.M. Edin., has been appointed Assistant Medical Officer to the City Hospital for Infectious Diseases, Edinburgh.

PROSSER, T. G., M.R.C.S., has been re-appointed Medical Officer for the Rockfield Sanitary District of the Monmouth Union.

RABY, L., M.D. Durh., M.R.C.S., has been re-appointed an Honorary Medical Officer for the Devizes Cottage Hospital.

ROSCOE, H., L.R.C.P. Lond., M.R.C.S., has been appointed a Resident Medical Assistant to the Dyffryn Aled Asylum, near Colwyn Bay.

TRUMPER, O. B., M.B., Ch.B. Vict., has been appointed Medical Officer for the Market Rasen No. 1 and the Tealby Sanitary District.

SELKIRK, J., M.A., M.B., C.M. Glasg., has been appointed Medical Officer for the Boston Spa Sanitary District of the Wetherby Union.

SHIRREFFS, WILLIAM, M.B., C.M. Aberd., has been appointed Medical Attendant for the Water, Sewage, and Roads Department of the Aberdeen Town Council, vice J. A. R. Glennie, resigned.

SLADEN, G. W. B., L.R.C.S. Irel., has been appointed Medical Officer for the Blyton Sanitary District and the Workhouse of the Gainsborough Union.

SMITH, R. R., L.R.C.P., L.R.C.S. Irel., has been appointed Assistant Medical Officer for the Walton Workhouse of the West Derby Union.

SUTCLIFFE, J., L.R.C.P. Edin., M.R.C.S., has been appointed an Assistant Medical Officer to the Cheadle Asylum.

THOMSON, G. D., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer by the Ruskington (Lincoln) Urban District Council.

TROW, A. V., M.B., C.M. Aberd., has been re-appointed an Honorary Surgeon to the Devizes Cottage Hospital.

TUXFORD, REGINALD, M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Resident Medical Officer to the Guest Hospital, Dudley, vice T. E. Hickman, resigned.

WAYLEN, G. S. A., L.R.C.P. Lond., M.R.C.S., has been re-appointed an Honorary Medical Officer for the Devizes Cottage Hospital.

WILLIAMS, J. T. C., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Whiteland District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—Out-patient Surgeon. Applications to the Honorary Secretary, Beechenhurst, Selly-hill, Birmingham.

THE RETREAT, York.—Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

UNIVERSITY OF SYDNEY, New South Wales, Australia.—Demonstrator of Physiology. Salary £350. Passage money allowed, £60. Applications to the Acting Agent-General for New South Wales, Westminster Chambers, 9, Victoria street Westminster.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea.—House Physician, for eight months. Honorarium at the rate of £50 per annum, with board and lodging in the hospital. Also House Surgeon for twelve months. Honorarium £50, with board, and lodging in the hospital.

Births, Marriages, and Deaths.

BIRTHS.

BATEMAN.—On Oct. 5th, at Devonshire-street, Portland-place, W., the wife of A. G. Bateman, M.B., C.M., of a daughter.

REICHARDT.—On Oct. 5th, at Dorset House, Ewell, Surrey, the wife of E. Noel Reichardt, M.B. Lond., of a daughter.

RUSSELL.—On Sept. 10th, at Subatha, Punjab, India, the wife of Surgeon-Major M. W. H. Russell, Army Medical Staff, of a son.

MARRIAGES.

BRIDGES—RIDLEY.—On Oct. 4th, at St. Stephen's, Avenue-road, Regent's-park, N.W., Ashley Colston Bridges, M.R.C.S., &c., Perth, Western Australia, to Miriam, youngest daughter of the late Edward Ridley, of Bridgnorth, Shropshire.

CAZALET—LYON.—On Oct. 2nd, at St. John's, Caterham-valley, Grenville William Cazalet, L.R.C.P. Lond., M.R.C.S. Eng., of Grey Friars green, Coventry, to Edith Louisa, eldest daughter of Jeremiah Lyon, Riddings Court.

CRAIG—MUNGALL.—On Sept 28th, at Balmoral Hotel, Princes-street, Edinburgh, by the Rev. John Sinclair, assisted by the Rev. James Aitken, M.A., William Craig, M.D., C.M. Edin., Foulford House, Cowdenbeath, to Isa Elder, eldest daughter of Henry Mungall, Esq., J.P., Woodside House, Cowdenbeath.

MORTON—LAW.—On Sept. 30th, at St. Bartholomew's, Maltby, by the Rev. J. Vernon, vicar, Samuel Ernest Morton, L.R.C.P., M.R.C.S., son of Samuel Morton, M.R.C.S., L.S.A., of 8, Burngreave road, Sheffield, to Mary Gertrude, eldest daughter of Wm. Law, The Manor, Maltby.

RITCHIE-THOMSON—POWYS.—On Sept. 28th, at St. Peter's, Wallingford, George Ritchie-Thomson, M.B. Edin., F.R.S.E., to Mabel Alice, second daughter of the late William Cunliffe Powys, Captain in H.M.'s 22nd Foot, and of Garden Creek, Fredericton, New Brunswick.

DEATHS.

CASSIDY.—On June 22nd, at Datta Khel, of wounds received on June 10th in the Tochi disaster, Surgeon-Captain Christopher Clemons Cassidy, son of the late Edward Cassidy, Derry, aged 32 years and 9 months.

FISHER.—On Sept. 19th, at Bawtry, Yorkshire, Jane, for 50 years the widow of the late George Fisher, M.R.C.S. Eng., L.S.A., of Bawtry, Yorkshire, aged 81 years.

KIRKMAN.—On Oct. 3rd, whilst crossing the Arabian Sea, Montague Kirkman, L.R.C.P. Ed., L.F.P.S. Glasg.

ROY.—At Cambridge, on Oct. 4th, Charles Smart Roy, M.A., M.D., F.R.S., of Trinity College, Professor of Pathology in the University of Cambridge, aged 43 years.

SMITH.—On Oct. 3rd, at Stockton Hospital, Robert Gillies Smith, M.A. Aberd., B.Sc. Lond., M.R.C.S., L.R.C.P., eldest son of Robert Smith, M.D., Durham County Asylum, aged 36.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

IMPRISONMENT FOR SELLING BAD MEAT.

AT Leamington on Monday last a drover was sentenced to three months' imprisonment for depositing for sale meat unfit for human consumption. The defendant having bought a cow for 12*s.* 6*d.* in a neighbouring town, slaughtered it, and offered the flesh for sale. The Mayor of Leamington pointed out that the health of the population could not be preserved if such offences were permitted, and very properly sent the offender to prison.

"THE ALFORMANT."

IN our notice last week of this apparatus for the disinfection of air by means of formaldehyde generated by heating tablets of "paraform" in a special lamp, it was stated that each tablet on heating yielded two and a half times its weight of gas. It should have read that each paraform tablet yielded formalin vapour equivalent in amount to two and a half times its weight of liquid formalin. A saturated aqueous solution of formalin contains 40 per cent. of gas, so that one part by weight of "paraform" is equivalent to two and a half parts by weight of liquid formalin. The discrepancy is pointed out in a communication which we have received from Dr. S. Rideal, who has very thoroughly investigated the disinfecting powers of formalin and its preparations.

Mr. George E. Clemow.—There can be no hesitation in affirming that it is not only inexpedient, but most improper, that the charge of wards for infectious diseases should be given to the same resident officers of a general hospital who have to conduct "major surgical operations, abdominal sections, &c." Indeed, the project of establishing such wards within sixty yards of the main building is fraught with danger. That the bacteriological laboratory should be conducted by the same officers is perhaps unwise, but less open to objection on the score of liability to the transmission of disease, since precautions could easily be taken. The laboratory would, we imagine, be mainly used as an adjunct to the clinical work of the institution, and the size of the hospital is not too great to prevent the officers devoting some of their time to such scientific investigations.

Enquirer (H. C. D.) is recommended to consult his medical man.

CHEAP JAM.

A CORRESPONDENT who ought to know writes to us as follows concerning a paragraph in our last issue: "I notice in THE LANCET a paragraph referring to the quality of the jam given to the inmates of the Bedwellty workhouse. The small sum of 2½*d.* per pound suggests at once to the uninitiated in practical details a sweet slush, or a miserable substitute for jam. I do not think this need necessarily be the case. At the present very low price of good sugar, and with the opportunities of securing sound fruits in bulk quite cheaply (which the commissariat department of public institutions ought to be on the alert to do), a good jam can be furnished at the figure named. I am talking now of home-made jams, and of course such jams may be spoilt by careless preparation. With regard to manufactured products, after the preparation of choice jams in large manufacturing establishments there are quantities of preserve often left not quite shapely in form, or up to the high standard of the particular market. A mixture of these remnants is retailed in some places at the low price of 1*s.* 6*d.* for seven pounds, and in larger quantities can be procured at a still lower figure. It is known as 'household jam' and is thoroughly good and wholesome. In conclusion I see no reason why a sound and palatable jam cannot be provided at 2½*d.* per pound."

Constant Reader (Southsea).—Articles on colitis have appeared in THE LANCET of the following dates: By Dr. Thompson, Nov. 28th, 1891 (p. 1220); by Dr. Goodhart, Feb. 13th, 1892 (p. 345); by Dr. Sainsbury, Aug. 13th, 1892 (p. 367); by Mr. Howard Marsh, Feb. 25th, 1893 (p. 414); by Dr. Carter, March 10th, 1894 (p. 610); by Dr. S. W. Wilson, Jan. 5th, 1895 (p. 75); by Mr. Wood, Jan. 12th, 1895 (p. 131); by Dr. W. H. White, March 2nd, 1895 (p. 537); by Mr. Skene Keith, March 9th, 1895 (p. 639); by Dr. Mackern, June 8th, 1895 (p. 1424) by Dr. W. H. White and Mr. Golding-Bird, Dec. 21st, 1895 (p. 1578); by Dr. Pye-Smith, Jan. 25th, 1896 (p. 233). For other references our correspondent might consult Neale's Digest.

Interested.—There are articles on Maternal Impressions in THE LANCET of the following dates: by Dr. Mackay, Dec. 19th, 1891, p. 1388; by Dr. Halket, Jan. 23rd, 1892, p. 212; July 7th, 1894, p 40; and Nov. 24th, 1894, p. 1233. We regret that we cannot give our correspondent a full bibliography from English and foreign sources, but we recommend him to consult Neale's Digest and Licetus de Monstris.

Enquirer (E. G. A. M.).—A vaccination officer holds office until he dies or resigns or is removed by or with the consent of the Local Government Board, to which body we recommend our correspondent to take his case.

TOSSING FOR A CORONER.

AT the Essex County Council, held at Chelmsford on Tuesday last, there was a tie in the voting for the coroner for the metropolitan district of the county, and the chairman of the council tossed up a coin, and upon head coming up declared Dr. Ambrose, of Buckhurst-Hill, duly elected.

PRESENTATION TO MR. W. J. C. MILLER, B.A.

WE recently announced that a fund was being raised, mainly by "educational" friends, to present a testimonial to Mr. Miller, late Registrar of the General Medical Council. The testimonial, consisting of a watch and purse, was presented to Mr. Miller on Friday, Oct. 1st. The watch bears a monogram, with the following inscription on the inner case: "Presented, with a purse of gold, to W. J. C. Miller, Esq., B.A., by friends and correspondents in England, America, India, and on the Continent of Europe, as a small token of personal esteem and in acknowledgment of his eminent services to mathematical science through the *Educational Times*. October, 1897." A complete list of the names of the subscribers to the fund was published in the *Educational Times* of Oct. 1st.

J. W. C.—So far as the improvement of the voice is concerned the earlier the false palate is employed the better, but the younger the child the more difficult it is to fix the obturator firmly, so that there may be no danger of its being swallowed. It must further be borne in mind that in children the false palate must be changed frequently to correspond with the rapid increase in size of the mouth which occurs in childhood. All these points being taken into consideration it may be said that a false palate should not be fixed until the child has attained the age of two or three years. If the employment of the obturator be delayed to a later age there is great probability that the nasal tone of the voice will be permanent.

Mrs. S. M. Bosanquet will find that we have made frequent allusion to the peril possibly latent in the chalice.

THE EULOGY OF QUACKERY.

To the Editors of THE LANCET.

SIRS,—This is a cutting from "Stray Notes" in the *Whitehaven Gazette* of Sept. 30th:—

> "There has been much talk lately about the wonderful cure effected to a Carlisle lady by the use of the water at St. Winifred's Well, at Holywell. . . .
>
> "After all is said and done, I don't see anything very miraculous in the cure. We all know how ignorant medical men are as a rule in connection with broken bones or dislocated joints. Even in Whitehaven cures have been effected in less than an hour of ailments that medical men have given up in despair.
>
> "Mr. Wilson, the bone-setter, of Aspatria, who attends the various market towns of the county once a week, has effected greater cures than this at Holywell, and no one attaches any extraordinary virtue to his treatment. He simply understands what he is about, and puts his knowledge into practice."

Comment is needless except to add that the opinion therein expressed is a very popular one in this part of the world, and that we are constantly subjected to censure by all classes because the bone-setter's diagnosis differs from ours. With the many associations and societies to which members of the profession are asked to subscribe for their mutual protection can nothing be done to stop this branch of unqualified practice? When will the public be willing to allow that it requires a braver and often more skilful man to confess doubt upon a point of diagnosis than to assert an absolute opinion, be it right or wrong, in all cases? I am, Sirs, yours faithfully,

Gosforth, Cumberland, Oct. 1st, 1897. C. H. POWERS.

*** The General Medical Council, it is hoped, will soon attempt to do something to stem the tide of quackery. It is in the meantime very regrettable that journals should publish these sweeping puffs of bone-setters. A little inquiry into the claims of such persons to knowledge or past success would always reveal their ignorance.—ED. L.

W. W.—Every case must be judged on its merits. We cannot guess what the Local Government Board might do without knowing the particular circumstances, but it probably has complete power to act as our correspondent describes.

A NURSE'S "MEDICAL AND SURGICAL SERVICES."

THE following advertisement appeared in a recent number of an evening paper:—

> SYDNEY.—A Lady, skilled Nurse, æt. 28, will Give her medical and surgical Services, or act as Companion to a Lady or special case, on a voyage to Sydney or to any port within 300 miles of there, and, if necessary, will stay a short time on arrival, in return for passage; highest testimonials up to date and diploma.—Address Dr. ——, York.

We should be glad to know what are the medical and surgical services of a nurse, what is the difference between a "lady" and "a special case," and what is the "diploma"?

Sigma is asked to sign a letter or give his address for publication, so that answers can be sent direct to him.

Digitized by Google

A POINT IN COLLIERY APPOINTMENTS.

DR. J. COWAN WILSON writes to us at some length concerning his position towards the practice in a colliery in his neighbourhood. The colliery in question has been until recently under the medical care of another practitioner residing elsewhere. Certain of the colliers having desired to be under the treatment of the medical man residing nearer them the medical officer offered to put an assistant in the place. But upon a ballot 143 colliers voted for employing Dr. Wilson, resident in the place, against 22 who did not wish to change. The manager of the colliery does not sanction any change and will continue to deduct the agreed weekly charge from the wages of the 22, and to hand it to the original medical officer. The 143 dissentients will not have this deduction made from their wages, but must make a collection among themselves for their medical man, which detracts from the safety and convenience of the appointment. Dr. Wilson's contention is that the majority having declared in his favour the same facilities should be given them with regard to their choice as are given to the minority who have decided to uphold their former medical man, and upon the face of it the argument has much force.

A PREDISPOSITION TO HERNIA?

To the Editors of THE LANCET.

SIRS,—A boy, aged seven and a half years, rather under the average size, has ridden a fat little cob since he was six years of age. He is comfortable in the saddle, can ride for ten or twelve miles without any fatigue, and is passionately fond of it. To my mind no harm can accrue, but everywhere I find the lay mind very much exercised as to the harm that will be done to him by putting him on such a wide mount. I find the general impression is that it will produce hernia, but I cannot see why opening the thighs in a light little boy should be any more dangerous than jumping about at play. The cob is very gentle and intelligent, in every way suitable otherwise, and I should be very sorry to have to change, but of course if there is anything in the popular idea I must not risk a rupture for the boy.

I am, Sirs, yours faithfully,

Oct. 3rd, 1897. THE FATHER, M.D.

*** As the inguinal canal is somewhat opened in the abducted thigh it is possible that if the thighs were kept for several hours daily in the abducted position the child would to some extent be risking a predisposition to hernia. The risk would not be great, but it would exist. We know of no observations on the subject.—ED. L.

Worried should consult his family medical man, who will respect his confidence.

THE GENERAL PRACTITIONER AND THE "NURSES' COÖPERATION."

A CORRESPONDENT has sent us for comment the following advertisement which appeared in *The Borough of Marylebone Mercury* of Saturday last:—

MIDWIFERY BRANCH.

Ings House. - - - - Nurses Co-Operation.
81, NEW BOND STREET, W.

Ladies are attended by Certificated Midwives at Fees from 7s. 6d.
(London Obstetrical Society.)
Matron can be seen privately every morning before 12 a.m.
All Cases must be booked and paid for beforehand.
Fully Trained Nurses are sent out for all cases.

TELEPHONE No. 5,109.
Telegrams, "OVERNIGHT," London.

He asks whether the London Obstetrical Society is aware of the way in which its name is being used, and quotes the advertisement as a striking example of the competition against which the general practitioner has now to contend. It would be interesting to know what the nurses would do if the case turned out to be a complicated one, for even certificated persons are not infallible. Would they tend for the nearest general practitioner to assist them or have they a particular medical man upon whose services they can rely by arrangement? In the former case is the medical man likely to be paid well when 7s. 6d. has already been obtained from the patient for inadequate services? In the latter case has the medical officer of the Coöperation considered that he is assisting in a dodge for obtaining the patients of his fellow practitioners?

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

A Lecture
ON
SOME TYPICAL FORMS OF CURVATURE OF THE SPINE.

Delivered at the City Orthopædic Hospital on Sept 29th, 1897,

BY NOBLE SMITH, F.R.C.S. EDIN., L.R.C.P. LOND.,
SENIOR SURGEON TO THE HOSPITAL, AND SURGEON TO THE ALL SAINTS' CHILDREN'S HOSPITAL.

GENTLEMEN,—The pathology of spinal curvature has not yet been thoroughly worked out. We know of caries, of cancer, of osteo-arthritis, of rickets, of lateral curvature, and of some few more rare conditions, and we talk of spinal weakness, which some of us call "neurotic spinal trouble," but further than this our text-books hardly carry us. Our museums contain a few cases of obvious osteo-porosis in which the spinal column has given way posteriorly or laterally, but instances of severe ordinary lateral curvature are so extremely frequent that skeletons showing very severe deformity are quite a common feature of our pathological collections. I would ask, Is it possible that the spine can give way either posteriorly or laterally, irrespective of caries, to the extent of the many severe cases of deformity which exist without there being some undue softness of the bones or unnatural laxity of the ligaments? It is the exact pathology of these cases which, I have suggested, is not sufficiently known.

All the above-mentioned conditions may commence with symptoms of ordinary weakness alone, and therefore it is of importance to deal cautiously with so-called "spinal weakness." Many a case of incipient spinal caries has been stimulated into severe activity by the "exercise treatment," whereas the plan which I adopted in the following cases would have been more suitable whether the case had been caries or debility alone. It is well known that the spine may give way laterally or posteriorly from weakness. Such weakness is often attributed to want of power in the muscles alone, but this view of the cause of the trouble does not coincide with certain facts which I have observed.

During the last eighteen years I have measured the backs of many hundreds of patients, and have found that when the body has been well developed for the age and the individual has been robust the length of the back from the level of the shoulders to the level of the chair in sitting has been equal to a measurement taken from the spine between the scapulæ round one shoulder back to the spine again. In a very large majority of the patients suffering from weak and crooked spines, the length of the back has been in excess of the shoulder measurement. The shoulders (which will generally be sloping downwards and forwards) should be brought back to a normal position at the time of measurement. The excessive length of back in proportion of the robustness of the body supports the view that weakness of the back is not so much due to muscular debility as it is to weakness of the spinal column itself—i.e., weakness of the ligaments accompanied not infrequently by undue softness of the bones. Debility from illness, from insufficient nourishing food, and rapid growth have seemed to be the most frequent causes of such want of stability in the spine. This view is supported by a number of facts, the most noticeable of which are recorded in the following history of a typical case.

A patient (say a girl about thirteen years of age) possesses a spine measuring one and a half inches in excess of the shoulder circumference (as above described); there is inability to sit up straight without assistance (that is the patient stoops perpetually), there is a complaint of almost constant or very frequent aching in the back, and when sitting there is to be seen a distinct lateral curve in one particular direction. By means of treatment, directed to preventing the spine from falling into bad positions without interfering with muscular action and improvement of the general health, the back gradually becomes straight and strong. The length of time during which the treatment will have to be carried out depends chiefly upon growth. Perhaps a year or eighteen months may elapse before the child will have "outgrown" her want of physical robustness. This result, however, will be attained sooner or later, and when it has happened treatment may be thrown aside absolutely. Measurement will then often show an adjustment of the dimensions, so that the shoulder measurement will be the same as the measurement of the spine.

There are, however, some individuals who grow up without efficient treatment having been adopted for this condition, and although they may have been able to follow their avocations in life fairly well, yet they are liable to suffer greatly from their weakness. They may develop scoliosis and become very deformed or kyphosis, and if the latter deformity is produced the symptoms may closely simulate those of caries, in fact it may be very difficult to decide whether any inflammatory disease be present or not, and those who have had most experience will probably have the greater difficulty in forming an immediate diagnosis. Fortunately it matters comparatively little at first what the exact nature of the weakness may be, for the treatment should be the same for a certain length of time in both cases, and during that time we shall have an opportunity of studying the affection sufficiently to arrive at a more definite diagnosis. Certain it is that we had better err upon the side of excessive caution than assume too readily the absence of inflammatory disease.

I am not referring to cases in which hysteria plays a prominent part, although it must not be forgotten that even hysterical patients may have real disease or real weakness, and when such a combination exists efficient treatment of the spine helps materially in overcoming the hysterical element. The following case is one in which there was undoubtedly great weakness and in which a suspicion of caries existed.

CASE 1.—A woman, aged twenty-two years, single, was sent to me by Dr. Buzzard on Nov. 8th, 1894. She had suffered for two years from pain in the back, chiefly in the lumbar region. This pain had been getting gradually worse until, a week before I saw her, she had been obliged to give up her work, which involved much standing about. She had not been without treatment directed to the improvement of her general health, and shortly before she came to me a surgeon had seen her and recognised the necessity of giving some support to her back. This he had attempted to do by means of a plastic felt jacket. The effect of this jacket was very unsatisfactory; the patient derived no benefit whatever from wearing it, but on the contrary felt the pain much worse. At the time of her visit to me she seemed to be extremely ill, with no other apparent cause than the weak back. Although the jacket was brought up much higher in the back than is usual and therefore might be thought to give more complete support than the ordinary jacket yet its effects in this direction were attained as usual at the expense of pressure upon the chest, and as this patient suffered from a chronic cough and much dysphagia any pressure upon the thorax and consequent interference with the free action of the heart and lungs was very detrimental to her. Several alterations in the position of the felt casing were made, but with little or no relief to the patient's sufferings. She was then told that the only course open to her was to go home and lie up entirely for six months. She thereupon gave up her employment, but before going away she consulted Dr. Buzzard, as it was supposed that her troubles might be due to some nerve trouble. Dr. Buzzard considered that all her pain came from weakness of the back and sent her on to me. By means of support with the "Adaptable Metal Splint" described elsewhere[1] the pain was quickly relieved, and instead of lying up for six months, she went back to work at the end of three days and never felt any more pain worth noticing. She steadily improved in health and strength, becoming much more robust.

In writing subsequently to me (April, 1897) she expressed herself as follows: "As soon as you put on the instrument I felt relief, and in three days afterwards I went back to my work, and could walk about without much pain. [A week previous to this she had not been able to move without extreme pain in the back and in the left thigh and leg.] In a fortnight I felt quite comfortable in the instrument, and from that time my general health began to improve. Three weeks afterwards I lost the cough which I had had for over a year, and it has never returned. I am very well now and can take longer walks, and can do much more than I have ever been able to do in my life." The subsidence of

[1] Caries of the Spine, second edition. London: Smith, Elder and Co. 1897.

Digitized by Google

cough is a very frequent result of this treatment and is doubtless due to the forced expansion of the lungs brought about by the apparatus. The treatment of this patient involved a very moderate amount of attention. During the first three weeks I had to see her about eight times, and after that only occasionally when the apparatus required slight adjustment in accordance with the patient's improving physical condition. Moreover, after the third day she was able to continue her work without interruption. In November, 1896, two years after her first visit, her back was quite strong and she did not require any further support.

CASE 2.—The next case is that of a patient in whom the symptoms were very similar to the last, but in whom the evidence of caries was stronger. A single woman, aged twenty-two years, came to see me in March, 1897. She had begun to feel pain in her spine about three years previously. During 1896 she was getting worse, and for the six months before the above date the pain had been constant. For the last four months she had, under medical advice, been resting almost completely—that is, she had walked downstairs in the morning, lain down on a sofa, and walked upstairs in the evening. She had given up all her work. The pain was described as dull and aching, but very severe, and it was just as bad after a night's rest as at any other time; she could not get into a comfortable position. Her suffering had gradually affected her general health, she was weak, anæmic, and had a very poor appetite. She had to be assisted from a cab into my room, and in sitting down she assumed the attitude shown in Fig. 1 (copied from a photograph) and could not sit up any straighter.

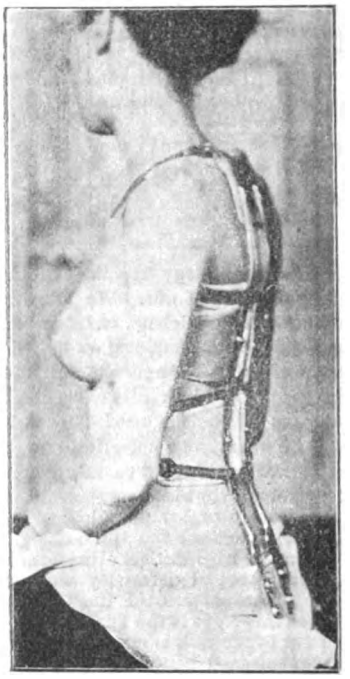

FIG. 1.

Showing the usual position assumed by the patient in Case 2 before treatment (March, 1897).

There was a slight excess of knee-jerk. The spinous processes of the ninth, tenth, and eleventh dorsal vertebræ projected rather more than the others, and pain was particularly severe in the region of these vertebræ, proceeding downwards and forwards. There was also aching pain upon each side of the whole spine, from the neck to the sacrum. The application of the adaptable splint at once afforded relief, and six days later the pain had completely left her. On April 6th—that is, eleven days after putting on the instrument—she felt so much improved in every way that she could walk a mile with comfort, and only felt anything of the former pain if she happened to move suddenly in the night. Two medical men who had seen her previously had attributed her symptoms to caries. I thought it probable that either this view was correct or that there was some other inflammatory condition of the vertebræ or intervertebral cartilages. Fig. 2 shows the patient on May 3rd, 1897, with

FIG. 2.

Showing the same patient on May 3rd, 1897, wearing the adaptable metal splint.

the apparatus on, and Fig. 3 shows her sitting up without the support at the same date, and without inconvenience. I did not think it advisable to let her try to maintain this position

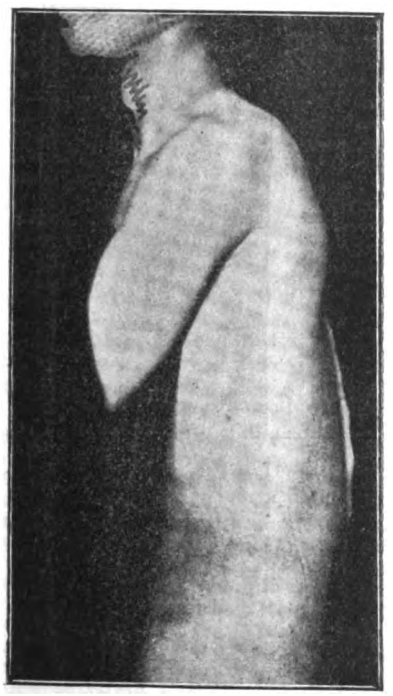
FIG. 3.

Showing the same patient on the same date after removal of the apparatus. She is sitting without any support.

for more than the few moments necessary for the photograph to be taken. Judging from other similar cases I should expect her to be quite well and strong in about a year from

Digitized by Google

the commencement of treatment, but it is probable that she will feel well and be able to do her work with the help of the apparatus some months earlier.



Subsequent to writing the above (June 12th) she expressed herself as feeling absolutely well, and in August she was doing some light work with perfect comfort. She came to see me on Sept. 17th. She had remained very well and only complained of feeling very tired after two hours' work at the desk. I examined her back again, and although the general contour of the spine was perfect yet the three vertebræ which at first had projected beyond the others were still seen slightly but clearly projecting, and upon movement of the body this part of the spine was rigid. I therefore came to the conclusion that it was a case of caries.

It is only during recent months that I have taken photographs of my cases, and therefore have selected this one and the following in preference to describing others of which I could record ultimately satisfactory results, but of which I have not photographic records. I have never met with any difficulty in giving up the use of the apparatus when the patients have become strong, although in some instances I have thought it advisable to supplement the treatment of local support by a short course of massage and sometimes a few gentle systematic exercises before advising the entire discarding of the apparatus.

There is rather a large class of cases in which the symptoms are somewhat similar to those recorded above, but in which there should be no suspicion of active caries, although the trouble may have originated in slight caries at some previous period of the patient's life. The following is a typical instance.

CASE 3.—A married woman, aged twenty-nine years, consulted me on Jan. 11th, 1897. She had been troubled with pain and a sense of weakness in her back since childhood, but there was no history of a definite cause. There was pain, chiefly between the shoulders and also in the lumbar region. This pain and a feeling of weakness had been gradually increasing and had lately become almost constant. The

FIG. 4.

Showing position of the spine in the patient in Case 3 when first seen on Jan. 11th, 1897.

general health suffered in consequence, severe headaches being a prominent symptom. If she attempted to walk it soon brought on pain and a feeling of weakness. She sometimes felt better for a night's rest, but not always. She had been married three years, but had had no children. Although the spine was obviously at fault inquiry was directed to the organs of the thorax and abdomen, but nothing more than functional disorder could be detected. The reflexes were normal as were also the various functions, although there was weakness of circulation and of digestion. Fig. 4 shows the position of the spine at the time of her first visit (Jan. 11th, 1897). She was not able to sit up any straighter, but upon pressure with the hands it was possible to move the spine in different directions, showing that there was no rigidity and therefore presumably no inflammatory mischief. She felt immediate relief from her pain upon the application of the splint, and the pain had entirely ceased in a week; the general health rapidly improved, and two months later (April, 1897) I was able to take the photograph represented in Fig. 5.

FIG. 5.

Showing marked improvement in the same patient in April, 1897. She is sitting up with perfect comfort.

This patient now requires very little surgical attention and will, I expect, be permanently cured when she has worn the instrument a few more months. She now only feels pain (in the lumbar region) when very tired. She has at my advice taken to cycling, which she can do with comfort. Her circulation and her digestion are now excellent and she is steadily gaining strength.

CASE 4.—Another somewhat similar case is that of a girl, aged twenty years, who had never been very strong, but was able to do a considerable amount of active manual work. She had for some years been liable to pain in the back and also to severe headaches, the origin of which was obscure. As regards the thoracic and abdominal viscera nothing but functional disorder was present, she being in much the same condition as Case 3, but neuralgia at the back of the head was very severe. Her ordinary posture in sitting was that shown in Fig. 6 from a photograph taken during her first visit to me (March 18th, 1897). She could sit up a very little straighter than this, but only with a great effort and for a moment at a time. The lower three dorsal vertebræ and all the lumbar vertebræ curved laterally to the left. Relief from the pain was felt immediately on application of the splint and quickly lessened; and I was able to straighten the spine rapidly, so that on April 3rd it had arrived at the position shown in Fig. 7, and on April 21st she stated that the headaches had practically ceased, having only occurred once during the previous few weeks, whereas before the treatment was commenced she suffered from headaches nearly every day, lasting all day, and this had been the case for years with a few intervals of about a month at a time. At this date

Digitized by Google

(April 21st) she also stated that she had never been so well as long as she could remember. Fig. 8 is from a photograph taken on May 3rd (six weeks and four days from her first visit) showing that she was able to sit up without a support.

FIG. 6.

Showing the usual position assumed by the patient in Case 4 when first seen on March 18th, 1897.

The lateral curvature was also much improved. I saw this patient again on Sept. 16th and found her apparently perfectly well, in almost robust health and spirits, and her back perfectly straight. She will wear the appiratus a few

FIG. 7.

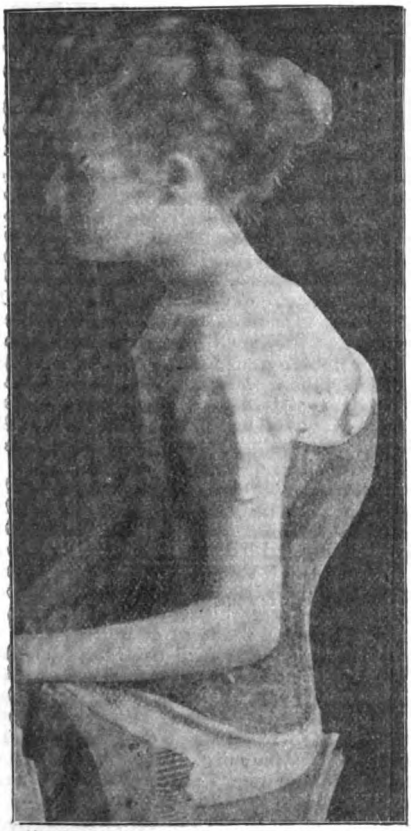
Showing improved position of the spine while wearing the support in this patient on April 3rd, 1897.

months longer, feeling absolutely no inconvenience from its use. I can promise her that when she gives it up she will only feel the want of it for a few days.

Another class of cases which have given rise to considerable trouble and in which treatment by apparatus is most valuable is that of elderly patients afflicted with lateral curvature.

CASE 5.—I saw a married woman, aged sixty years, on April 16th, 1889, at the request of the late Sir Russell Reynolds. This patient had suffered from severe pain and aching in the back for some years, chiefly in the lumbar region. Her symptoms gave rise to much difference of opinion as to their cause, and she had recently been seen by an eminent surgeon who had diagnosed a bony growth in connexion with the left crest of the ilium, close to the spine. There was only slight lateral curvature in the spinous processes of the lumbar vertebræ to the left. This was clearly a case of lateral curvature in which the rotation of the vertebræ existed with very little deflection of the spinous processes, and the "bony tumour" was composed of the transverse processes and the bodies of the rotated vertebræ. These are rare cases in comparison with the ordinary forms of lateral curvature. One very remarkable instance—that of the late Dr. Gideon Mantell—was recorded by Mr. W. Adams, in which the spinous processes formed

FIG. 8.



Showing marked improvement in the patient of Case 4 after less than seven weeks' treatment.

an absolutely straight line while the bodies of the vertebræ were rotated into a severe curve. I have also recorded some similar cases. Various palliative remedies had been tried for this patient but had failed to relieve her, and the deformity was increasing. I applied an adaptable metal splint with a single bar and a specially made pad to support the rotated vertebræ. This afforded her relief and stopped the progress of the deformity, but owing to the great severity of the displacement of the vertebræ there was more difficulty than usual in attaining quite a comfortable position. The patient also was aging rapidly, and died on Dec. 31st, 1890, so that she only wore the instrument nine months. I am indebted to Lady Russell Reynolds, who knew this patient, for the information that after the last re-adjustment which I made on Sept. 26th, 1890, the patient had more ease and comfort.

The relief from pain in these cases greatly depends upon one's ability to support the ribs from contact with the crest of the ilium. The spine in the last recorded case was greatly rotated in the lower lumbar region, and I was only just beginning to succeed in relieving this contact at the date of that last visit. I give this case as one of the most difficult I have had to deal with, and it shows that even under such

FIG. 9.

Showing the depression of the chest and roundness of the back in the felt jacket.

FIG. 10.

Showing the effect rapidly produced by the adaptable metal splint

adverse circumstances a deformity can be stopped from increasing and relief given to the patient's suffering.

With regard to the plastic felt jackets which are so commonly used in the present day when a support is required, I would remark that they are not satisfactory in their mode of action; they press on the chest, but do little towards holding back the shoulders; they interfere with the use of the muscles, they interfere with the evaporation of perspiration, and they fail to give efficient support. The following figures show the ineffectiveness of the ordinary felt jacket in controlling the position of the spine and the immediate effect of applying the adaptable metal splint.

The metal splint has the following advantages: 1. It leaves room for action of the muscles. 2. It develops the chest and does not press upon it. 3. It prevents the spine from subsiding into bad positions. 4. It forms a fixed basis from which to apply pressure upon lateral curves. 5. It enables the surgeon to see the effect upon the spine while the apparatus is *in situ*. 6. It is made of steel, the lightest material for the purpose, which is so tempered that it can be bent into any form by the surgeon himself. 7. It is comparatively light and is so helpful to the patient that a weak child can do more with it on than without it. It may be accepted as an axiom that whatever position the spine is held in by means of the adaptable metal splint that position will in time become permanent.

NOTE ON THE WOUNDED IN THE NAVAL BATTLES BETWEEN JAPAN AND CHINA DURING 1894-95, WITH SOME CONSIDERATIONS OF SANITARY CONDITIONS PREVAILING DURING THE WAR.[1]

BY S. SUZUKI, M.R.C.S. ENG., L.R.C.P. LOND.,
FLEET-SURGEON, IMPERIAL JAPANESE NAVY.

IN the Japan-China war during 1894 and 1895 the naval battles at Phung-do and Yalu, the attacks upon Tangchow, Wei-hai-wei, and the Pescadores were the principal engagements; the bombardments of Hwa-yuan-kow, Talien Bay, Port Arthur, Yingching Bay, and Keelung, Takau, and Anping in Formosa are also reckoned as sea-fights of importance. The naval battle of Phung-do on July 25th, 1894, was fought between the *Yoshino*, *Naniwa*, and *Akitsushima*, forming the first flying squadron of Japan, on one side, and the *Tsi Yuen*, *Kwang-yi*, and *Tsao-kiang* of the Chinese fleet, on the other side, the *Yoshino* receiving two shells in her side and the *Naniwa* receiving one, also in her side; but no material damage was done, neither was any one killed or wounded. From other cause, however, three persons on board the *Yoshino* had their membrana tympani perforated, and three on the *Naniwa* were slightly injured by burns. Attacks upon Tangchow were made by the Japanese warships on three occasions; firstly by the *Yoshino*, *Naniwa*, and *Akitsushima* on Jan. 18th and 19th, 1895; secondly by the *Tenryu* and *Kaimon* of the Third Flying Squadron, on Jan. 26th; lastly, by the *Tenryu*, *Yamato*, and *Musashi* of the above squadron on Feb. 21st. The forts on Tangchow replied to our attacks with volleys from their heavier or lighter guns. Though the *Kaimon* received two shells in her side there was no actual damage to our squadron and no case of killed or injured. The attack upon the forts on the Pescadores occurred on March 23rd, 1895; the Japanese combined squadrons, composed of the *Matsushima*, *Itsukushima*, *Hashidate*, *Naniwa*, *Takachiho*, and *Akitsushima* leading the transports carrying a mixed detachment, subjected the Kon-peh-tai fort to a fierce bombardment. The Chinese garrison replying to this with volleys from their heavy guns, the engagement continued for five hours. But no shell struck our warships and the guns on the Fort were silenced after having been nearly destroyed. During this engagement the mixed detachment landed on Li-sei-kakû and marched to the interior. At dawn the next morning each war-ship ordered a landing

[1] A paper read before the Twelfth International Medical Congress held at Moscow Aug. 19th to 26th, 1897.

Digitized by Google

party to advance as a reinforcement to the army. On March 25th the whole of the islands surrendered to the Japanese. During the course of the fighting only one person on the *Naniwa* was wounded receiving a fracture of the lower jaw and a lacerated wound of the neck from the deliberate aim of the enemy. He was immediately treated by a surgeon belonging to the landing party and afterwards sent back to the naval hospital of the Port Admiralty at home, where he quite recovered, a deformity of the lower jaw being left. In regard to the above-mentioned battles there were no actual damages on our side as I have already narrated, I shall therefore only give the surgical statistics of deaths and injuries resulting from the Battle of Yalu, and the attack on Wei-hai-wei with a general review of sanitary conditions. When the "History of the Health of the Imperial Japanese Navy in Relation to the Japan-China War," which is now being compiled, is published we shall be able to see the details of the sanitary conditions during the war.

THE BATTLE OF YALU.

It was on Sept. 17th, 1894, that the Japanese combined squadrons, composed of the Principal Squadron, which comprised the *Matsushima*, *Itsukushima*, *Hashidate*, *Fuso*, *Chiyoda*, and *Hiyei*; the First Flying Squadron, which comprised the *Yoshino*, *Naniwa*, *Takachiho*, and *Akitsushima*, and the gunboat *Akagi* with the ex-merchant steamer, *Saikyomaru*, transformed into a cruiser for the time being, fought on the Yellow Sea with the Chinese fleet, consisting of the *Ting Yuen*, *Chen Yuen*, *King Yuen*, *Lai Yuen*, *Ching Yuen*, *Chih Yuen*, *Ping Yuen*, *Tsi Yuen*, *Yang Wei*, *Chao Yang*, *Kwang Chia*, *Kwang Ping*, and two torpedo boats. The great battle was commenced at 12.50 P.M. and closed at 5.30 P.M. Our warships received more than one hundred shells in various parts and the number of persons killed or injured amounted to 298. The tables which follow give the details for the number of persons killed or injured in this battle. The highest numbers of killed or injured were on board the following vessels: (1) the *Matsushima*, (2) *Hiyei*, (3) *Itsukushima*, and (4) *Akagi*, &c.; but if we consider the ratio of killed or injured we find the numerical order to be as follows—viz.: (1) the *Matsushima*, (2) *Akagi*, and (3) *Hiyei*, with the *Saikyomaru*, *Itsukushima*, *Akitsushima*, *Fuso*, *Hashidate*, *Yoshino*, *Takachiho*, *Naniwa*, &c. From the fact that the numbers of killed or injured on board the *Matsushima*, *Akagi*, and *Hiyei* were especially numerous it is easy to imagine what an important part these three warships played in the action. Comparing the number of killed or injured according to their rank, the most numerous are seamen, being 57·38 per cent.; next come petty officers and officers, with 16·44 per cent. and 10·07 per cent. respectively; the lowest are the civilians, with 2·35 per cent.; while the other non-combatants account for 6·38 per cent. in each class. As the number of persons in each rank differs much it is difficult to estimate the real ratio from the above percentages. The percentage-ratio of killed or injured to the number of persons engaged, however, shows little difference between the different ranks, except that the non-combatants indicate the maximum, while the stokers and blacksmiths represent the minimum. In all engagements on land the infantry had always more killed or injured than the artillery, engineers, and sanitary corps, because the former approach nearer to the enemy than the latter. In sea-fights, however, any person above the water line of a warship may be easily injured by the enemy's shells irrespectively of his work; thus seamen who are exposed on barbettes to the discharge of shells, or non-combatants working on the main deck—in fact, all those who are working above water line—are equally liable to be killed or wounded. As our ships were not perforated by any shell below the water line during this war those who were working below it were safe; the natural result is, therefore, that the number of persons killed or injured belonging to the engineering class, who were always working below the water level, is the smallest. On board the *Itsukushima* five persons of the engineering class were killed or injured at one time owing to the explosion of a 15-centimetre shell, which perforated a starboard coal bunker in midships 3 ft. above the water line and crushed a ladder in the boiler-room of the afterpart.

The number of killed or injured includes those who were injured by the vibration of air caused by the firing of their own guns—viz., five men on board the *Itsukushima*, one on the *Hashidate*, one on the *Yoshino*, two on the *Naniwa*, and one on the *Takachiho*. It is not proper to make calculations based on an inclusion of persons killed or injured in this way. Therefore, subtracting these cases from the number of killed or injured the following ratio is found—that is, the *Itsukushima*, 3·3 per shell; the *Hashidate*, 1·1 per shell; the *Yoshino*, 1·4 per shell; the *Naniwa*, 0·0 per shell; and the *Takachiho*, 0·4 per shell. The order arranged according to the magnitude of ratio of the number of killed or injured to the number of shell hits is as follows: the *Matsushima*, *Akitsushima*, *Itsukushima*, *Hiyei*, *Fuso*, *Yoshino*, *Hashidate*, *Akagi*, *Saikyomaru*, and *Takachiho*. On board the *Naniwa* and *Chiyoda* there was no case of killed or injured by the shells of the enemy. The order simply calculated according to the magnitude of the number of shell hits is *Akagi*, *Hiyei*, *Saikyomaru*, *Hashidate*, *Fuso*, *Naniwa*, *Matsushima*, *Itsukushima*, *Takachiho*, *Akitsushima*, *Chiyoda*, and *Yoshino*. But the number of killed or injured is not necessarily proportionate to that of shell hits. Of shell hits, some were from heavier and some from lighter guns; some burst and others did not burst; while others were only pieces of shells. Thus the degree of damage is different according to the kinds of shells or the result of bursting. When the shells burst the damage was always greatest, the *Matsushima* having 30 persons killed at one time and 70 persons injured (half of these owing to the explosion of gunpowder itself) by a 30·0 centimetre shell, the *Hiyei* 14 persons killed and 27 persons injured by a well-directed shell of the same kind, the *Itsukushima* 8 persons killed and 3 persons injured by a 21 centimetre shell, and the *Akitsushima* 5 persons killed and 9 injured by the same kind of shell. On board the *Itsukushima* 4 persons were killed and 6 persons injured by the bursting of even small shells of 50 millimetres. Though the *Saikyomaru* was hit with 30·5 centimetre shells on her side and the *Chiyoda* with 21 centimetre shells in the same part, yet little damage was done, because the shell only perforated the ships' sides without bursting. Quoting one more example: in the naval battle of Phung-do a 15 centimetre shell hit the *Yoshino's* deck-house and passed down to her engine-room rolling about there around the men, but it did not burst fortunately, so no one was killed or injured. Thus we may see how much the number of casualties depends on whether the shells burst or not. The reason why the number of exploded shells is not proportionate to the number of killed or injured is conditional upon circumstances; for example, if there was no one near the place where the shell burst there was no case of killed or injured, but when the opposite was the case the result was a great number of casualties. It must be remembered that, moreover, fragments of ships' planks, &c., or "indirect-shot" gave heavy damage to our ships. For example, the funnel of the *Fuso* having been perforated by a shell the fragments of it dispersed around and either killed or injured ten seamen. The bursting of the shell of the *Hiyei* either killed or injured forty-one seamen; of this number more than ten men were either killed or injured by the indirect shot.

TABLE I.—*The Seat of Injuries.**

Seat of injury.	Number of killed or injured.	Ratio of seat of injury according to number of killed or injured.
Greater part of the body	57	19·13
Various parts of the body	24	8·05
Head	66	21·15
Neck	7	2·35
Chest and back	19	6·38
Abdomen and lumbar region ...	25	8·39
Upper extremity	55	18·46
Lower extremity	45	15·10
Total and ratio	298	99·01

* As most persons injured had several wounds the above table classifies according to the severity of the wounds. But it is impossible to classify the complete destruction of the body and extensive burns as one particular part of the body. These fatal injuries are analysed in Table III.

Of the total number of 298 killed or injured the part of the body most liable to be wounded is shown in Table I. thus. The number of head wounds was the greatest, the ratio being 21·15 per cent. of the total number. Next in

Digitized by Google

order came the wounds of the greater part of the body, of the upper limbs, of the lower limbs, of the abdomen and lumbar region, of the various parts of the body, and of the chest and back, while the fewest injuries were in the neck. Leaving out the number of wounds of the greater part of the body and the various parts of the body from the total number, the number of wounds of the head stands first, followed in order by those in the extremities, the abdomen and lumbar region, the chest and back, the last and fewest being those of the neck. In a land-fight the number of wounds of the lower extremity is commonly greatest and that of the upper extremity and head next; then come the chest and back, abdomen and lumbar region, and the neck wounds are the fewest. Now, comparing the number of wounds received in a land-fight with those received in a sea-fight it is found that they are almost identical. The only marked difference between them is that in the former case the greatest number of wounds received are those of both extremities, the head wounds coming next, while in the latter case the head wounds are the most numerous, and those of both extremities come next. This difference is but natural, because in land-fights soldiers are injured only by shells and bullets (though there are some exceptions), but in sea-fights all materials around the combatants, as ship's planks and rigging, &c., being blown to pieces by the bursting of shells, increase the causes of injury.

* Including invalided. † Died from erysipelas.

By Table II. it will be seen that the greatest number of immediate deaths, or deaths shortly supervening, occurred from injuries under the title of injuries to the greater part of the body. This is a natural result, because the destruction of the body by burns which extended over one-third of the body are included in this column. The sum total, viz., 57 cases in this column (with the exception of 2 cases of burns over one-third of the body), terminated in death. The numerical order of immediate death or death shortly supervening is as follows: of the head, the lumbar region and abdomen, the lower extremity, the chest and back, the neck, and the upper extremity. Under the headings of the various parts of the body, the face, spinal region and spinal cord, there were no deaths, but under the headings of chest and back, abdomen and lumbar region and lower limbs, the number of immediate deaths is comparatively great, because, unlike wounds perforated by rifles, the greater part of the body was crushed or destroyed or the viscera and the large blood-vessels were destroyed by the pieces of shell. As the wounds were so severe some died a few minutes after the injuries received, none surviving more than four days. The details will be found in Table III.

These deaths took place before admission to hospital. I will now say a few words about those who died after admission to hospital. 1. Of three persons who were burned over one-half of the body two died three days after admission and six days after receiving the injury, and the third nine days after admission and twelve days after the injury, the mode of death being by coma in each case. 2. One person whose skull was penetrated by a fragment of a shell above the right frontal eminence followed by symptoms of compression of the brain died from coma, notwithstanding trephining fifty-three days after admission to hospital and fifty-six days after the injury. 3. Of two persons who received a penetrating wound of the abdomen the ribs of the one were fractured by the fragment of a shell which passed through the left false rib and penetrated the thoracic and abdominal cavity crushing the abdominal viscera; when admitted to hospital peritonitis

* Except two the whole number of complete destruction of the body belonged to the *Matsushima*. Though this number was returned by the surgeon on board we believe there may be included in it some who were thrown out into the sea by explosion of ammunition and lost their lives.

had already commenced, making his condition unfit to undergo laparotomy, and he died from exhaustion five days after admission and nine days after injury. The other one received a penetrating wound of the left umbilical region from a fragment of shell injuring the intestinal canal at several points; the intestinal contents passed out into the abdominal cavity causing peritonitis, and he died from exhaustion thirty-eight days after admission and forty-one days after injury. 4. One person had a compound fracture of the lumbar region from the fragments of the planks of the ship penetrating the sacro-iliac joints into the pelvic cavity and rupturing the bladder; he died from exhaustion thirteen days after admission and seventeen days after the injury. 5. One person, who had severe compound fracture of the right scapula and humerus, nearly recovered after admission, but unfortunately was attacked with erysipelas six months after and died within a fortnight after the complication, the whole course of illness lasting 179 days after admission and 181 days after injury. 6. One person had a compound fracture of the right thigh by a shell, destroying the thigh bone below the great trochanter, severing the soft tissues, and rendering it hopeless to attempt conservative treatment, so amputation at the upper part of the thigh was performed, but he died from exhaustion complicated with traumatic delirium twelve days after admission and fifteen days after injury.

All injuries, except the cases of gangrene resulting from injuries of blood-vessels in compound fractures and wounds of joints, were treated with antiseptic precautions and as a consequence no infectious diseases of wounds occurred except in one person, who died from erysipelas.

KILLED OR INJURED DURING THE ATTACK UPON WEI-HAI-WEI.

After Jan. 30th, 1895, our combined squadron and torpedo flotillas moved against Wei-hai-wei with a strong force. The enemy's forts, coöperating with their squadron in the port, defended themselves to the utmost; but they were no match for the furious attacks of our squadron or the bold attack of our torpedo flotillas, and the bombardment from the captured forts at last led to the surrender of the enemy on Feb. 12th. In this battle our war-ships received twenty-eight shells, and sixty-six persons were killed or injured. (Tables IV., V., and VI. show the details.) Forty-six shells which struck above ships were discharged from the forts of Jhih and Liukung Islands. While our landing party on the captured battery of Lau-cha-tsao at Wei-hai-wei was bombarding the enemy's warships which were anchored in the port the party received a 30·5 centimetre shell discharged from the *Ting Yuen* and the two shells discharged from the *Tsi Yuen*, by which seven men were either killed or injured. During the attack by our torpedo flotillas on Feb. 5th No. 9 boat received thirteen shells from the enemy, and as one of them struck the boiler of the boat eight persons were scalded. During the next day's attack No. 22 struck against a reef below the Lung-miao-tsai Fort on her way to the anchorage. At this critical moment two persons on the boat jumped into the sea, hoping to reach the shore by swimming, but the extreme cold prevented their bodily motion and they were drowned. Three of the others tried to reach the shore in a canvas boat, but on their way the boat was upset and one man died from the extreme cold; the other two, though suffering from severe frost-bite, reached the shore by swimming.

THE SANITARY CONDITIONS DURING THE WAR.

The sanitary improvements which we have been gradually effecting for many years have always borne good fruit in the decrease of patients statistically and the annual increase of body weight; but this was especially the case during the late war. From the beginning of the Imperial Japanese Navy up to 1883 the sanitary condition of the navy was in a very slow state; for example, the men-of-war sent to distant seas or those despatched to Corea during the outbreak of troubles in that country (1882) produced many patients, especially those suffering from kak'ke, an endemic disease in the east. Kak'ke was predominant from 1878 to 1883, there being 30, or 40 per cent., of cases of kak'ke among seamen, which produced the deaths of forty or fifty seamen every year. Had there been a collision with any other nation at that time it would have been very perilous for us to open war under such circumstances. Since 1882 a committee for preventive measures against kak'ke was appointed, and after thorough investigation it was decided that kak'ke originates from improper administration of food — that is, too large a quantity of carbohydrates, as rice, and too little of albuminoids, as meat; so since 1884, by diminishing the quantity of rice and increasing that of meat for the seamen's rations, an improvement in the scale of diet was put into practice. Since then, as we anticipated, the cases of kak'ke suddenly decreased, and the health of the seamen in general being promoted, not only kak'ke, but all other diseases of seamen were diminished. Thus kak'ke was nearly extirpated in 1886. At the same time that the improvement in the scale of diet was effected a rule was made that the body-weight of seamen should be taken in March and September every year, with a view to ascertaining the sanitary conditions of seamen as affected by the new scale of diet. Previously to the improvement of diet the average individual weight of body was 52 50 kilogrammes, but after the improvement the weight increased considerably year after year. Though the general health of our navy had made such excellent progress as a result of the improvement in the scale of diet, yet some fears were expressed with regard to the health of the navy at the commencement of the war, on account of our having had no experience of sanitary conditions during war-time. But trusting to our sound principles, already put into practice for many years, we maintained routine regulations as to diet with most successful results, as will be seen in the following table of patients (Table VII.). The number of killed or injured is excluded from the table, which shows the number of patients in the navy in general from July, 1894, to December, 1895. During this time the total number of cases of diseases was 7106, the average cases of disease per day being 12 94. Those patients who were employed under actual service are included in this number of cases, so that the number of patients who lost their duty entirely is less than the number above mentioned. The average percentage of days' sickness

Digitized by Google

per 100 of force was 3·71, being only an increase of 0·25 when compared with the average ratio 3·46 of the last five years. The total number of deaths during these eighteen months was 215, the percentage ratio to the total force being 1·06. If we subtract 35 cases of drowning (an unavoidable occurrence in seafaring life) and 3 of suicidal death from 215, the number of the real deaths from disease was only 177, being a loss of 0·87 per cent. If we compare the number of deaths with that of killed (150) the former is greater than the latter by only 27. As the number of deaths (177) includes seamen in general, without distinction between seamen on active service or seamen on duty at home stations, the number of deaths on active service is less than 177 in reality. A glance at the ancient and modern history of battles will show that the number of deaths have generally exceeded the number of killed; sometimes the former was many times greater than the latter. Though there is some difference between sea-fights and land-fights as regards sanitary matters, yet such a comparatively small number of deaths is a proof of the satisfactory health of our navy.

THE GENERAL SICK-LIST.

Of the principal diseases of the appended table (see Table VII.) the number of cases of venereal disease and its sequels is 37·69 per cent. of the total number of cases of disease. This may be regarded as an evil resulting from the war. The number of injuries (persons wounded exclusively) is 13·86 per cent. of the total number of cases of disease, and that of diseases of the digestive system is 10·09 per cent. These diseases were much more frequent during the summers of 1894 and 1895 than in the other seasons, and may be partly attributed to debility of gastric function in the summer. The number of cases of diseases of the respiratory system is 9·01 per cent. of the total number. These diseases were especially prevalent in the winter of 1894. The cause of it is attributable to the severe climate of the northern localities, such as Talien Bay, Port Arthur, and Wei-hai-wei, at which most of our ships were stationed. The reason of the diminution in the same diseases in the winter of 1895 is that many of our vessels returned home or cruised to warm southern climes, as Formosa. The number of diseases of the integumentary system is 8·91 of the total number. These diseases mostly occurred in the summer of 1894 and diminished gradually month after month. At the commencement of the war, when every preparation was in haste, our seamen could not take warm bathing or wash their clothes regularly even in hot climates. Sometimes when coolies were scarce they were obliged to coal their ships themselves — a fact which sufficiently accounts for the prevalence of diseases of the skin at this time. The total number of infectious diseases was 603—that is, 8·49 per cent. of the total number of all diseases.

One case of scarlet fever occurred on board the *Omimaru*, but the disease did not spread. Of the total number of 131 cases of typhoid fever, 55 cases (about one-fourth of the total number of the complement) occurred on board the *Yamato* during the expedition to Formosa. A few of the rest occurred on other ships abroad or at home stations, but the sickness did not spread. The character of the fever was somewhat malignant and 24 men (18·32 per cent. of the total number of cases of the disease) died from it. Of the total number of 95 cases of cholera, of which 48 cases occurred on vessels and the remaining 47 cases at shore stations, 52 or 54·74 per cent. of the total number of cholera cases died. The greater number of cases of cholera occurred on board the *Omimaru* (10), in the Naval Barracks of Yokosuka (10), at the Defensive Mine Station of Sasebo (10), in the Naval Barracks of Kure (9), on board the *Kaimon* (7), and *Matsushima* (6). A few cases of the disease occurred on other vessels or shore stations. During the operations at the Pescadores cholera broke out in some companies of the Imperial army, and it prevailed throughout the army in general. At this time landing parties from the navy were sent to reinforce the army; also our surgeons and medical attendants gave helping hands in the treatment of numerous patients in the army, and conducted the disinfection of soldiers, &c. Under such difficult and dangerous circumstances it is a matter for congratulation that only three persons of our navy were infected with cholera. It is, then, easy to infer how satisfactory were our preventive measures against infectious diseases. Of 83 cases of dysentery, 5 or 6·02 per cent. of the total number died. The disease occurred principally among the colliers in the Base station of "Longreach" in Corea (20), in the naval barracks of Kure (12), on board the *Fuso* (8), and on the *Matsushima* (5); a few

cases of the disease occurred on other vessels or at some other stations. Of 167 cases of malarial fever, 8 or 4·79 per cent. of the total number died. The disease principally occurred on board the *Yamato* (23), *Yoshino* (21), *Akitsushima* (10), and *Yayeyama* (10) which were despatched to Formosa, and on the *Chokai* (13) which was sent to Peh Yang or the northern sea of China; a few cases of the disease occurred on board some other vessels. Seventeen cases of fever occurred in the stations of Sasebo, six in those of Kure, seven in those of Yokosuka, and three in the special service party on the captured territory at Liaotung peninsula. With regard to small-pox we were quite victorious, as there was no single case notwithstanding our forces have traversed Chinese or Corean territory where sporadic cases of small-pox are always to be found; this is undoubtedly due to our strict rule of revaccination for all seamen, &c., every five years. Of the 43 cases of kak'ke 3 died, the ratio of cases per 100 of force being 0·21. The forty-three cases of kak'ke occurred on board the following vessels, viz.: the *Takachiho* (12), *Matsushima* (3), *Atago* (3), *Omimaru* (2), *Akashimaru* (2), *Akitsushima* (1), *Kongo* (1), *Katsuragi* (1), *Yamato* (1), *Tenryu* (1), *Kaimon* (1), *Amagi* (1), *Maya* (1), *Shinagawamaru* (1), *Genzanmaru* (1), *Yedomaru* (1), and *Genkaimaru* (1). The others occurred at the following shore stations, viz.: the Naval Barracks at Kure (3), the Naval Barracks at Sasebo (2), the Gunnery training ship (1), the Naval Barracks of Yokosuka (1), the Naval Barracks of Port Arthur (1), and the Base station of Long-reach in Corea (1). As already mentioned, an improvement in the scale of diet was effected after 1884, and in consequence this disease had diminished year after year until it had been nearly extirpated in the navy. The disease, however, broke out afresh. Let us examine why this was. In April, 1894, the *Takachiho* was despatched to Hawaii, and as soon as she returned she was repaired with extraordinary speed. After her repairs were finished she immediately sailed for the expedition. As the seamen of the ship suffered from a comparatively poor supply of fresh food they ate too large a quantity of rice. Of the twelve patients of the *Takachiho* ten were stokers, whose hard work in the boiler-room at a high temperature in a hot climate caused them to drink water to excess, in consequence of which they disturbed their digestive organs. Under such circumstances it was that so many cases of the disease occurred on the ship. The three patients of the *Matsushima*, suffering from a poor supply of fresh food and eating too large a quantity of rice, overworked themselves in the hot climate of Formosa. The two patients of the *Omimaru* and the one of the *Akitsushima* did not eat too large a quantity of rice, but both suffered from a poor supply of fresh food and overwork in the hot climate of Formosa. The one patient of the Maya always disliked meat and was fond of liquors; as the one patient of the *Kaimon* had a great taste for sweet articles he celebrated his return home by eating sweets to excess and disturbed his digestive organs. The three patients of the *Atago*, one each of the *Kongo*, *Katsuragi*, *Amagi*, and the Base station were obliged to take preserved food for a long time during the expedition, and took a dislike for preserved meat and hard biscuits toward the end of the expedition. The two patients of the *Akashimaru* and the one each of the *Shinagawamaru*, *Genzanmaru*, *Yedomaru*, and *Genkaimaru*, with the two of *Sasebo* and one of Kure Barracks (the last three men were from the crews of transports who were enlisted after the occurrence of the disease), did not take regular food while on board the transports because these vessels are not war-ships and not under navy regulations. The other case from the Kure Barracks was a second-reserve man who had already suffered from the disease before the call. The one patient of the naval barracks of Port Arthur was attacked by kak'ke after the occurrence of rheumatism. One patient from each of the *Tenryu*, *Yamato*, and the Yokosuka Barracks disturbed their digestive organs by over-eating and over-drinking after returning home after a long stay in camp. The cause of two cases of kak'ke—one in Kure Barracks and one on the *Yokosuka* gunnery training ship—is not certain. Summing up the above mentioned I conclude that the cases of kak'ke directly originated from want of proper food and indirectly from the impossibility of taking proper food which resulted from injury of the digestive organs from certain cause. Hence the principal cause of this disease is undoubtedly due to improper and bad food. To ascertain how the war affected the constitution of the forces the body weight of the force was calculated. Its result was that in 1894 the average individual body weight of the force amounted to 58·238 kilogrammes, but in 1895 it had increased to 58·463 kilogrammes. Comparing these weights with those already mentioned it is found that the body weight during war showed a greater increase than before. This, I take it, is a proof of the excellent health of our naval forces.

Tokio, Japan.

TWENTY-SIX CASES IN WHICH AN ABDOMINAL SECTION HAS BEEN PERFORMED A SECOND TIME.[1]

BY JOHN D. MALCOLM, M.B., C.M., F.R.C.S. EDIN.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

IN this paper I include every case in my practice in which an abdominal section has been performed a second time,[2] with the exception of six cases already recorded.[3] I have selected these cases for publication together because their histories illustrate a considerable number of complications, accidents, and causes of death which may occur in abdominal surgery, and because very few of them are without special points of interest. The cases may be divided into three groups. In the first eight the second operation was performed on account of a return of disease after a period of good health. The second group consists of five cases in which the first operation was insufficient to effect a cure. In the remaining thirteen cases the second operation was required on account of some complication arising as an immediate or a remote consequence of the first.

GROUP I.

CASES 1, 2, and 3.—The first three cases were examples of the growth of an ovarian tumour in the second ovary after the removal of an ovarian tumour. In Case 1 the second ovary had completely separated from its normal connexions, probably by twisting, and was nourished by adhesions in its abnormal position. The patient is alive and well. In Cases 2 and 3 the patients very nearly died from obstruction of the bowel during convalescence. The former is alive still; the latter died from pneumonia at the age of sixty-five years, nearly five years after the second operation.

CASE 4.—In this case an ovarian cystic tumour had been removed by another surgeon three and a half years before I saw the patient. I diagnosed a second cystoma, but on opening the abdomen I found a very large collection of ascitic fluid, encysted by peritoneal adhesions. The left ovary and tube were absent. The right appendages were dotted over with a granular growth which might have been either tuberculous disease or papilloma. I removed the ovary and tube and the patient made a good recovery.

CASES 5 and 6.—In these cases it was supposed that both ovaries had been completely removed for neoplasms before the patients came under my care. In each case I was informed of this by the gentleman who had operated. Nevertheless, I performed in each case an operation in no way differing from an ovariotomy with deep enucleation of the growth except that the Fallopian tubes were absent. Both cases recovered. These two cases show a local recurrence of an ovarian growth. The condition is in marked contrast to the secondary development of malignant disease which took place in the following case.

CASE 7.—In this case I performed a fairly easy ovariotomy on June 6th, 1893. The patient made an uncomplicated recovery and continued in good health until October, 1895, when she began to suffer from an increasing difficulty in keeping the bowels open. I saw her on Jan. 26th, 1896, and she then had an almost complete intestinal obstruction with abdominal distension, pain, and vomiting. I recommended an exploration with the formation of a fistula to relieve the vomiting and the pain due to peristaltic efforts, if no more

[1] Abstract of a paper read before the Medical Society of London.

[2] The operation of paracentesis abdominis has not been considered an abdominal section, although it might be maintained that the abdominal cavity is opened thereby.

Digitized by Google

effectual treatment should be possible. The peritoneum was found studded over with numerous cancerous nodules and I therefore opened a coil of gut and made an artificial anus. The operation was successful in relieving pain, but death from exhaustion took place a month later.

CASE 8.—The gentleman who performed the first operation in this case informed me that he had found an ovarian tumour so thin-walled and so deeply embedded in the broad ligament that he thought it wise to drain the tumour instead of removing it. When I opened the abdomen, nine years later, I found a multilocular very thin-walled cystoma of the right ovary and commencing disease of a similar nature on the left side. I had no difficulty in removing both completely. It is now two years since the operation, and the patient is stout and well, nothing abnormal being palpaple in the pelvis.

In the foregoing cases I performed both operations in only two instances, the first and seventh. Death was not caused by the operation in any of these cases, and six of the patients are alive and well.

GROUP II.

In the following five cases the first operations failed to effect a cure. In each instance I performed the second operation only, and there were two deaths.

CASE 9.—The left ovary was removed from the patient in May, 1890, for the relief of inflammation accompanied by constant aching pain. After about two months the pain returned in the remaining ovary. The patient became so ill that, after consultation with the gentleman who had performed the first operation and with others, I removed the second ovary in March, 1891. The patient suffered much for about a year after the operation. She then began to improve, and last spring she informed me that she only suffered from a bearing-down sensation of comparatively little consequence.

CASE 10.—This patient dated her illness from 1881, when she was much shaken and frightened by an accident. A few months later she began to suffer from profuse, frequent, and painful menstruation. In 1885 she sought advice at one of our metropolitan hospitals. Something was removed through the vagina, but no benefit resulted. Early in 1893 an abdominal section was performed by the obstetric physician to another London hospital. After this the patient could not get about at all. A profuse red discharge from the uterus continued for three or four weeks at a time, and it was considered necessary to plug the vagina on several occasions. The pain was so great that injections of morphia were required almost daily. After ten months a ligature escaped from the vagina and there were subsequently repeated discharges of matter and blood. The gentleman who had operated told me that he had removed the left ovary, which contained a small dermoid tumour, and also the right ovary, but he was not sure if he had removed the latter completely. I reopened the abdomen on March 22nd, 1894, and after separating many adhesions I removed the left Fallopian tube with a small nodule that was evidently the tied stump of the left ovary. Part of the right Fallopian tube also remained, and it was removed together with that part of the broad ligament to which the ovary should normally have been attached. Two small pedunculate fibroids—the largest about the size of a walnut—were then tied off and cut away, and I noted that there were numerous other small fibroids in the uterine wall. Convalescence gave no trouble. After the patient got up uterine discharges continued at intervals till August, but there was then no blood in these discharges. I saw the patient in June, 1895. She was then in the best of health, without any pain or discharge. Obviously the arrest of the functions of the uterus was essential to a cure in this case, and this had not been effected by the first operation.

CASE 11.—In this case the patient complained of a swelling in the abdomen and of having had much pain for six years. During that time she had attended a hospital for women and had been an in-patient twice. In April, 1895, an abdominal section had been performed, and since that time the patient's health had been much worse than before, the pain had been more severe, and the periods had been very irregular. On examining her I found extreme tenderness in the pelvis, which made it impossible to define the parts with certainty. The womb, however, seemed somewhat enlarged, and I detected two swellings—one the size of a Tangerine orange on the left side and a smaller one on the right, this last being much the more tender of the two. The woman was in a state of great exhaustion from constant suffering, and every examination caused excruciating pain, which only subsided after two or three days. Her pulse was never below 120, and the temperature varied between 97·4° and 99° F. On June 1st, 1896, about thirteen months after the first operation, I re-opened the abdomen and found that the fundus uteri was retroverted. I found three interlocked silk ligatures in a cavity between the right broad ligament and the sigmoid flexure. I carefully removed the walls of this cavity and also the left ovary and tube, which formed an inflamed mass the size of a Tangerine orange. The patient died on the third day, with a high temperature and a rapid, feeble pulse. At the necropsy there was no evidence of peritonitis, and there was no fluid in the peritoneal cavity except a few drachms of blood-stained serum. I attribute this death to the severity of the operation and to the exhausted and poisoned condition of the patient.

CASE 12.—In this case a fibroid tumour was cut down upon by the patient's medical attendant in 1891, but nothing was removed. Afterwards a cystic tumour was tapped on several occasions, and in May, 1893, a cyst was opened and drained. Other tumours developed in the abdomen, and in July, 1894, the gentleman who had operated brought the patient to me for advice and further treatment. The patient was then forty-seven years of age and had ceased to menstruate. When I had made a careful examination the patient and her friends were plainly told that an operation would involve unusual danger, but as the tumours were very large and partly cystic I advised that they should be removed, and the patient decided to have this done, with the full approval of the gentleman who had performed the first operation. Accordingly, on July 25th, 1894, I removed the part of the uterus above the cervix with two solid and two very large cystic fibromata. There were very strong and extensive adhesions caused by the first operations, and two of the tumours required very deep enucleation from the left broad ligament. The ovaries and Fallopian tubes were also removed. The adhesions on the right side were so tough that their separation required a very difficult and prolonged manipulation. After an operation lasting nearly three hours the patient was put to bed in very fair condition, but she died seventeen hours later with symptoms which indicated that a ureter or the bladder had been injured. I did not think the latter could have been wounded because in separating it from the enlarged uterus I had had a catheter passed as a guide until I thought I was working well behind the bladder. At the necropsy, however, an opening was found in the posterior wall of the bladder near its base. I can only offer a conjecture as to how and when the accident happened. I presume it must have been when I was enucleating the smaller solid tumour which was situated deeply in the cellular tissue to the left of the vagina. As I have said, I thought when I was enucleating this growth that I was working below the bladder, and I kept a keen look out for the ureter, which, however, I did not see. At this part the tissues were very vascular, and the catheter used to define the position of the bladder had also emptied it, so that I got no assistance from the sudden gush of urine that might otherwise have taken place. I think that probably the left ureter was pressed low down by the tumour in the deep part of the broad ligament, and that a portion of the bladder had been drawn down with it. The post-mortem report stated that the bladder was very large. This accident was most distressing, for the patient's chance of recovery would have been fairly good if it had not happened. I record the case because it is necessary to complete the series, and also because it shows how the ordinary anatomical relations may be distorted by pelvic growths.

CASE 13.—The last case in this group was a most unpromising one. The patient was forty-four years old and had had her ovaries removed by the obstetric physician to one of our metropolitan hospitals in May, 1893, for the purpose of arresting hæmorrhage caused by a uterine tumour. Her periods ceased for six months after the operation and then returned, blood being constantly lost in small quantity and very copiously for a few days about once a month. On two subsequent occasions the patient had some operation performed through the vagina, an anæsthetic being given. The second of these minor operations was performed in November, 1895, and there was no discharge after it, but the tumour began to grow rapidly and became very painful. The patient decided to seek advice at the Samaritan Free Hospital, where she was admitted under my care on July 6th. She had a tumour of the uterus rising to the level of the navel, with an irregular surface and

Digitized by Google

very tender. It expanded the cervix uteri down almost to the external os, but it was fairly movable from side to side at its upper part. Those of my colleagues who saw the case advised that the tumour should be removed, although it was obvious that the patient was very feeble. I agreed that an operation alone could give relief. Nevertheless, I should have hesitated about undertaking such an obviously dangerous course if the patient had not urged me to do so after I had clearly expressed to her my opinion that the result would be very doubtful. On July 16th I performed hysterectomy, fixing the cervix of the uterus, secured by a serre-nœud, between the lips of the wound. When this can be done I believe it gives the patient a far better chance of recovery than any of the methods by which the abdomen is at once closed. The patient gave no trouble from a surgical point of view during convalescence, although she was in a position of extreme danger for weeks on account of her debility and the state of her lungs. I saw her on Oct. 5th, 1896, when her wound was quite healed; she was free from pain and had put on much flesh. Microscopically the tumour was a round-celled sarcoma. In the spring of 1897 this patient was successfully operated on by another surgeon for acute obstruction of the intestine. I am informed that now (October, 1897) she is very ill and not expected to recover.

GROUP III.

In the remaining cases the second operation was performed on account of some complication resulting from the first operation or arising during convalescence. In this group I performed both operations in six cases. In the other seven I performed the second operation only. Five of the patients died. The first three cases in this group indicated three forms of bowel difficulty which may arise after an abdominal section.

CASE 14.—The patient when I first saw her was forty-four years of age, and had been under treatment for uterine tumours in America for eleven years. She had constant and increasing pain, which was more severe at her monthly periods. I was at first inclined to take the view which had probably been taken by others—namely, that an operation for the removal of the growths was unjustifiable when the patient might shortly hope for relief by passing through the change of life. After keeping her under observation for about six months, however, I came to the conclusion that she really did suffer sufficiently to justify surgical interference. On opening the abdomen, I found that there was in each iliac region a very hard oval tumour the size of an orange attached to the top of the uterus by a pedicle about one and a half inches long and as thick as an ordinary cedar pencil. These growths were almost devoid of blood-supply and had undergone a kind of calcareous degeneration, so that they were practically foreign bodies. They had created much inflammation and were attached by adhesions to everything they touched. Without doubt these adhesions were a chief cause of pain. In addition to the above there was a large, soft fibroid tumour tensely filling Douglas's pouch. I removed all the tumours and also the ovaries and Fallopian tubes and fixed the stump of the uterus outside the peritoneum in the usual way. Convalescence was complicated by the fact that every attempt to feed the patient by the mouth gave rise to pain, retention of flatus, and abdominal distension, these unpleasant conditions ceasing when nutriment was administered only by the rectum. This alternation of conditions was repeated over and over again, the pulse and temperature being only very slightly affected. The bowels were moved from time to time by enemata, but the administration of these also gave much pain, and laxatives always caused distension. Two months after the operation I ordered that feeding by the mouth should be persevered with for a few days. The result was that after four days the pain became very severe and culminated in a kind of fit. Under rectal feeding the patient returned to her usual condition; but after this attack she was able to take food more freely, and laxatives had more effect than before in moving the bowels. I believe that some adhesions gave way at this time. The patient left my immediate charge a fortnight later with instructions to be very careful in keeping the bowels open and to limit the diet if she became distended. I hoped that the partial obstruction which evidently existed would be overcome in time by the gradual stretching of adhesions. The patient continued to be much troubled by pain and distension. She could not take laxative medicine or use an enema without suffering severely, and the bowels would not act spontaneously. After an interval of twenty-two months I agreed to the patient's urgent request that I should re-open the abdomen and separate the adhesions which I believed to be the cause of her trouble. On Oct. 16th, 1895, I opened the abdomen and found that the centre of the transverse colon was fixed to the back of the abdominal incision nearer to the pubes than to the umbilicus, so that this portion of the gut had a V-shape, and the acute angle at the middle of the colon was at the time of operation occupied by a scybalous mass of fæces. The omentum was much adherent to the abdominal wall and also to the sigmoid flexure, which was thus fixed to the centre of the transverse colon. I separated the transverse colon from the omentum and put it in its proper place. The patient made a good recovery, and her bowel condition was much improved. She still complains of distension and pain in the right side, but Mr. Thorburn Steer, under whose observation she has been recently, tells me that the attacks of pain are certainly less troublesome as time goes on.

CASE 15.—The next case illustrates a remote and rare effect of a pelvic operation. The patient had a double ovariotomy performed in 1882. This was followed by troublesome constipation, which became a serious difficulty ten years later. She came under my care in May, 1893, when no treatment either by the rectum or by the mouth made the slightest impression on the bowels. This condition had developed very slowly. The finger in the rectum could not reach the seat of obstruction, but large masses of fæces were felt both through the rectum and through the vagina, and also by palpation of the abdomen. There was no rise of temperature. After consultation I opened the abdomen on June 2nd, 1893 and found the whole colon enormously distended, but I could not find the cause of obstruction. As there had been no fever, and the patient, although very weak, was not acutely ill, the small gut not being distended, I decided to sew the sigmoid flexure to the wound and to open it later. By 8 P.M. on the day of operation, however, the patient's condition was extremely serious, the pulse being 140 and the temperature 102° F. It was obvious that the bowel must be opened without further delay. This was done and a large quantity of fæces was removed, but death occurred about midnight. At the necropsy it was found that there had been no escape of fæces into the peritoneal cavity. At the lower end of the sigmoid flexure the canal of the gut was almost completely obstructed by a mass of cicatricial tissue which had ulcerated on the mucous surface. The lumen of the canal was reduced to the size of a cedar pencil and passed obliquely through the diseased tissues. It is easy to say now that in this case it would have been wiser to open and clear the bowel at the time of operation.

CASE 16.—This patient had a supra-vaginal hysterectomy performed in 1893, from which she made a good recovery. She continued well until March 22nd, 1896. On the evening of that day she ate a hearty supper, and on the following morning she was seized with severe pain in the abdomen. I was asked to see her on the 24th, when I found the pulse 72 and the temperature below 100° F. To the left of the middle line I could define a distended coil of intestine which I thought might be the sigmoid flexure. Further consultation was desired, and as a consequence operation was postponed. In the meantime opium and belladonna were given, food by the mouth was withheld, and the patient was nourished by nutrient enemata. Next morning the pulse was 108, the temperature was 103°, and the abdomen was somewhat distended. I opened the peritoneal cavity and found a coil of small gut strangulated and sloughing. It had been tightly constricted by a band of adhesion which was very strong although not thicker than a piece of No. 3 Chinese silk. I washed out the peritoneal cavity and made an artificial anus; but diffuse septic peritonitis already existed, and the patient died about 10 o'clock in the evening of the day of operation. Surgical treatment cannot be employed too soon for the condition which existed here, but it is not always easy to decide beforehand when to operate. Cases of obstruction by band if promptly treated should give as good results as the operation for strangulated hernia. Unfortunately, the diagnosis is more difficult and the initial treatment is too often a purgative.

In the next two cases, Nos. 17 and 18, the second operation was required on account of a hernia in the scar of the first.

CASE 19.—Though the peritoneum was not opened this case is included in the series because the kidney is an

Digitized by Google

abdominal organ. The patient had lost a great deal of pus from the right kidney for five years before I saw her. I drained the organ, giving great relief, but four weeks later an obstruction in the left ureter necessitated a left nephrotomy. The patient died three days after the second operation.

CASE 20.—In this case an unusually adherent dermoid ovarian tumour was removed on June 11th, 1896, and the patient's condition gave no trouble or anxiety for a fortnight. On the sixteenth day she was allowed to get up and lie on a sofa, and she then complained that her belt hurt her. Two days later there was a rise of temperature. The patient was confined to bed again and I discovered a decided tenderness in the left kidney which was enlarged. I then obtained a history that for eighteen months the urine had from time to time been thick when passed. The specimen which I had examined before operation became very slightly hazy on boiling. The urine passed during the first fortnight of convalescence was abundant, acid, and clear, but I did not examine it for albumin. On July 3rd, the twenty-second day after the operation, some urine was passed containing about half its bulk of pus. After this the patient's condition improved somewhat and the urine again became clear and contained only a trace of albumin. There was no trouble from the bowels. The lower abdomen was soft and flaccid, and no hardness or tenderness was detected in the pelvis by bimanual examination. The left kidney remained very tender. On July 6th, the twenty-sixth day after the operation, the patient's condition was again worse; the left kidney was very hard and could not be touched without causing severe pain; the temperature rose to 105°, and the pulse, which had kept steady, about 84 to the minute, rose above 100. The patient became drowsy and indifferent, and I expressed the opinion that she would die if an opening were not made into the left kidney. On July 7th, in consultation with Sir Douglas Powell and Mr. Coker, of Uxbridge-road, it was agreed that the kidney should be opened, and this was done immediately. The kidney was not less than nine inches long, and broad in proportion. On tapping it with a trocar and cannula I drew off some red fluid but no pus. I therefore made an incision into the pelvis, but still got no pus. On inserting my finger I found that the calices were much enlarged, and I divided several septa, pushing my finger into the kidney in all directions, but gaining no further information as to the cause of mischief. The parts outside the kidney were quite normal. I inserted a drainage-tube and closed the wound. The patient was very feeble for a couple of days, and the temperature remained high, but after July 9th the course of convalescence was one of steady improvement. Later it was discovered that these attacks yielded promptly to purgation, and Mr. Coker suggested that free purgation might have obviated the necessity for the second operation. This is just possible, although I hardly think it likely. It did not occur to any of us to treat the case in this way at the time of serious danger, and the bowels were then being frequently moved without difficulty. It should further be considered that although I discovered nothing but a much dilated kidney at my second operation I must certainly have altered the relations of its calices to each other by my manipulations, and that in this way I may have broken down some obstruction to the exit of urine. I am inclined to think that this patient had suffered from pressure of the tumour on her ureters, especially the left, for many months before operation, that the kidney was distended occasionally, and that when she got up after lying on her back for a fortnight the left kidney was tilted over and induced a valve-like obstruction, which was closed by the pressure of the fluid within the kidney, and relief was not obtained till the kidney was opened. At the second operation I probably removed some valve-like obstruction such as is described by Fauger in the Annals of Surgery for June, 1896.[4] In July, 1897, this patient's health was thoroughly re-established.

In the following six cases an immediate operation was deemed necessary during convalescence from various operations. In two cases I performed both operations, and the results were fatal. In the last four cases I performed the second operation only and all recovered.

CASE 21.—The patient was a woman, aged thirty-five years, in whom extreme anæmia had been induced by profuse hæmorrhages caused by the presence of a fibroid uterine tumour. The patient was very feeble, but on the ninth day after hysterectomy the bowels had acted freely, the sloughing pedicle seemed to be separating nicely, the patient enjoyed her food, and I thought all would be well with her. On this day I made a note that the wound above the pedicle was free from all signs of irritation, and I removed all the sutures except those next the sloughing pedicle. The following night the patient was restless and uncomfortable. On the twelfth day after the operation I found that about an inch of the upper part of the incision had yielded, exposing the omentum. There was no sign of adhesion or other inflammatory reaction. I carefully cleaned and re-closed the opening by three sutures, but the patient gradually sank and died thirty-six hours later. At the necropsy there was no evidence of inflammation in the abdomen except some injection of peritoneum behind the seat of rupture of the wound. There was much congestion of the lungs, and all the tissues were very anæmic. I have seen a considerable number of cases of rupture of the abdominal wound due to a sudden strain, as from retching or coughing after the sutures have been removed, but I have never seen any other than this, in which there was no attempt at union of the exposed viscera to the edges of the incision, or any in which a fatal issue has resulted from the accident.

CASE 22.—This patient was a woman, aged forty years. There had been a uterine discharge for six years, which had constantly increased and had been very offensive for about two years. The uterus had been curetted by one of my colleagues in February, 1896, but a microscopic examination of the scrapings had not indicated that the disease was malignant. After a time, however, a clinical diagnosis of malignancy was made, and I was asked to remove the uterus. When I saw the patient her womb was slightly enlarged and was discharging great quantities of offensive matter, and as a consequence she was extremely anæmic. Removal of the uterus seemed possible, and the patient, although made fully aware of the serious nature of operative treatment, was most anxious to take the risk. My colleagues with whom I consulted thought an operation was justified as affording the only chance of relief. I therefore agreed to open the abdomen and to perform hysterectomy if the disease seemed confined to the womb. I performed this operation, but cancerous disease had almost destroyed the whole circumference of the uterine wall at the inner os. In the evening, although the patient was very feeble, her condition, both physically and mentally, was satisfactory. Next day she appeared to be doing well in many ways. She had passed ten ounces of urine in the night without the aid of a catheter, and had had some quiet sleep. Flatus had escaped when a rectal tube was passed, and there had been no vomiting. The temperature had risen to 102·2° F. in the axilla, but had come down to 99·6° by 10 A.M. The pulse, however, was extremely feeble, had risen to 140, and during the afternoon the heart failed still more. Early in the afternoon the patient suddenly collapsed, the temperature falling to 97° and the pulse becoming uncountable. When I saw her a little later she was evidently moribund but still sensible, and the condition seemed to me to simulate the effects of hæmorrhage so closely that, after I had ascertained that there was no escape of blood from the vagina, I determined to re-open the abdomen. The patient was so ill that no harm could result if there was no hæmorrhage, and it did not seem right that I should leave the question of the possibility of the existence of hæmorrhage undecided. The second operation was a very trivial one—merely the removal of a few sutures and the insertion of the finger—but it might have been a very important procedure, as in Case 24, and it brings the case within the title of this paper. The patient died an hour later. At the necropsy some coils of intestine were found to be adherent in the pelvis, and there was some turbid serum there also, but no blood. It was undoubtedly an error of judgment to yield to this patient's desire to be operated on; but I have always been guided in this question by the view that if there be any doubt as to the course to be adopted, that is, if I think there is any chance at all of benefit being derived from an operation, the patient should be allowed to decide for or against this course if he or she has been made clearly to understand the risks involved.

In the last four cases in my list I was fortunate in being able to perform successful operations in emergencies occurring in the practices of others.

CASE 23.—In this case the operations were the same as in Case 21—namely, a hysterectomy and a re-sewing of a

[4] The Operative Conservative Treatment of Sacculated Kidney. Annals of Surgery, June, 1896.

Digitized by Google

ruptured incision on the eleventh day. But in this case the patient was a strong woman; her wound gave way suddenly during the night, and when I examined it some hours later I found the protruding bowel firmly adherent to the divided edges of the incision. I cleaned the parts, returned the viscus, and sewed up the wound, which did not give any further trouble.

CASE 24.—I was asked to see a patient about two hours after a hysterectomy had been performed. She had suddenly become very pale and faint whilst in the act of retching. When I saw her she had every appearance of severe hæmorrhage. As the gentleman who had operated was not at hand I opened the abdomen, found that its cavity was full of blood, and that the right broad ligament had slipped completely from its ligatures. I re-secured the divided broad ligament and removed large quantities of blood, but I did not wash out the abdominal cavity because healthy blood-clot is not likely to do harm. A glass drainage tube was placed in the pouch of Douglas. It was doubtful for many hours, indeed for days, whether the patient would survive; but she gradually rallied and made a perfect, though slow, recovery. She was alive and well five years after the operation.

CASE 25.—In this case the inverted fundus of the uterus simulated a polypus, and had been removed by means of scissors, the nature of the operation being discovered by examination of the specimen. I saw the patient within an hour, and although her condition did not appear serious I thought it best to ensure against hæmorrhage by opening the abdomen and securing all the bleeding points. The second operation was begun within two hours of the first. Very little bleeding had taken place, but the disturbance of the parts set up free hæmorrhage, and there can be little doubt that the patient would have run a very serious risk when reaction set in if the hæmostatic power of nature had been trusted to. I tied the uterine arteries and broad ligaments and sewed together the divided uterine surfaces so as to close completely the opening from the vagina to the peritoneum. The patient made a perfect recovery.

CASE 26.—The accident that occurred in this case is, I believe, very rare. In dressing a patient whose pelvis was being drained I discovered on the fourth day after operation that the glass drainage-tube was fractured. I removed some sutures and fished up the lower half of the tube with a pair of forceps, the blades of which were guarded by rubber tubing. The two pieces of glass accurately completed the tube. Another tube was inserted for twenty-four hours. Beyond a sharp rise of temperature and pulse, which was recovered from next day, the accident caused no trouble and it did not delay convalescence.

The two great dangers in operating on the abdomen are the introduction of septic mischief during the operation and the occurrence of obstruction of the bowels or of pseudo ileus after the operation. In the foregoing cases I have succeeded in avoiding a fatal issue from these conditions, although in all the fatal cases septic mischief was primarily or secondarily an important cause of death. If a patient has to be operated on when the blood is already saturated with the products of septic mischief, as in Cases 16, 22, 11, 15, and 19, it is very difficult to avoid a fatal issue from septicæmia. But besides septicæmia and bowel complications there are many dangers and accidents which may occur in connexion with an abdominal section. The bowel conditions in Cases 14, 15, and 16 indicate remote dangers. The cancerous recurrence in Case 7 is a condition of great importance. Many accidents and mistakes are illustrated in my paper—injury to the bladder, Case 12; rupture of the abdominal wound, Cases 21 and 23; slipping of ligatures, Case 24; and mistaking of an inverted fundus for a polypus, Case 25. All these accidents have occurred before, and doubtless they will occur again; but I think that by bringing these together I may impress on operators the necessity for the greatest care during and after operations so that these and other dangers may be avoided.

Portman-street, W.

THE NEWPORT (MON.) WATER-SUPPLY. — A special meeting of the County Council was held on Sept. 28th to consider the present condition of the Wentworth Scheme for the water-supply of Newport. Many failures have from time to time occurred during the course of the work, and the chairman mentioned that the cost of the undertaking up to the present had been £100,408.

ETIOLOGY OF DIPHTHERIA, WITH SPECIAL REFERENCE TO TWO LOCALISED OUTBREAKS IN WANDSWORTH.

BY P. CALDWELL SMITH, M.A., M.D. GLASG., D.P.H. CAMB.,

MEDICAL OFFICER OF HEALTH OF THE PARISH OF WANDSWORTH.

To all sanitarians as well as to medical men generally the increased prevalence of diphtheria in London is a subject of the greatest importance, and any addition, however small, to our knowledge of the etiology of this disease ought to be carefully studied for future guidance. It has been well said by Dr. Creighton in his admirable book on the History of Epidemics in Great Britain that "diphtheria is, perhaps, the most obscure and complex of all the infectious diseases in its causes and favouring conditions" and its continued prevalence in the metropolis has verified the above statement. The death-rate for diphtheria in London for the ten years 1871–80 was 120 per million living; in 1881–90, 260 per million; while in the year 1893 this rate was 740; in 1894, 610; in 1895, 520; and in 1896, 602 per million. On the continent the death-rate is in some towns higher than the 1895 rate, it being in St. Petersburg 590 per million and in Berlin 540; while in Paris, Brussels, Amsterdam, Vienna, and Rome the rate was in the same year lower, in the latter city being only 80 per million. The above statistics tend to modify the view that insanitary conditions in dwelling houses are the cause of diphtheria, nor do they altogether agree with the statement of Sir R. Thorne Thorne that "sewage gas produces a morbid condition of the fauces rendering the patient more liable to the reception of the diphtheria poison." In the first place there is no doubt that in London the sanitary condition of the houses of the working classes is much better than it was in the decennium 1871–80, when the diphtheria mortality was 120 per million, as compared with 602 per million in 1896; and in the second place it is certain that the general sanitary arrangements in London are superior to those existing, not only in continental towns, but also in provincial towns in England and Scotland, which have a much lower diphtheria mortality. That it is even a predisposing cause would also seem to be negatived by the same statistics, so that for practical purposes we are confronted with the only other possible sources of infection—viz., infection by milk and infection from person to person. In this regard the remarks made by Bristowe in his "Theory and Practice of Medicine" may be quoted. He says that "there is reason to believe that the sanitary state of houses and localities and the condition of health of those who are exposed to its poison have much influence over its development." That was the general and accepted professional opinion twenty years ago, and even yet it is maintained that sanitary defects play an important part in its causation. Again, we know that the zymotic disease most intimately related to insanitary conditions is enteric fever, although even in this the specific organism must be present before infection can occur. Specifically polluted milk, water, and other articles of food are of course the most common causes of outbreaks of enteric fever, but, as has been stated by Dr. Theodore Thomson, "there is no doubt that the air of sewers and drains which has become specifically contaminated may, if allowed to find its way into dwellings through defective house connexions, cause from time to time enteric fever among the inhabitants of such dwellings."

If, then, the sanitary condition of the metropolis has been improved we would expect a gradual diminution in the typhoid fever death-rate, and this is what has taken place. The death-rate which was in the decennium 1871–80 240 per million fell to 190 per million in 1881–90, 140 per million in 1895, and 127 per million in 1896. These figures would lead one to believe that the sanitary condition of the houses in the metropolis is better now than it has ever been, and yet we see that the diphtheria mortality has increased from 120 to 602 per million in twenty years. Seeing, then, that insanitary conditions do not explain the great rise in diphtheria mortality some other method of infection must be looked for. Dr. Klein, after elaborate research and experiment, came to the conclusion

Digitized by Google

that cows can be infected with the diphtheria bacillus, and that the milk from these cows, if drunk, would produce diphtheria in the human being. It is not denied by sanitarians that milk, if infected from a human source with the diphtheria bacillus (for milk is a good medium for the growth of this bacillus), will produce the disease in persons drinking it; but whether this disease of cows is true diphtheria, or the bacillus described by Klein is similar to the Klebs-Löffler bacillus, has not, as far as I am aware, been definitely determined by other authorities. The only animal in which it is probable that diphtheria occurs is the domestic cat, and several cases have been traced to infection from this source. In the cat no membrane has ever been observed on the fauces or larynx, and the principal organs affected are the lungs and kidneys. No doubt the bacilli are exhaled and expelled in the mucous discharge, and in this way infection of human beings may take place. It is important to note in this connexion that it is now decided that the affection of fowls and pigeons in which a membranous growth occurs in the throat has no connexion with diphtheria in human beings. One certain mode of infection is by fomites, and although this will not explain all cases yet many have been recorded proving that the virus can be conveyed by persons or things. I know of one case, or rather one household, that was infected in which the poison was conveyed by a letter, as has often happened in the case of scarlet fever. Jacobi is of opinion that diphtheria is exquisitely contagious, that the germ clings to body-linen, bed-linen, clothes, and wood-work, and furniture of rooms in which a case had occurred.

Far more important than the probable causation by defective sanitary arrangements, specifically infected milk, domestic animals, and fomites is the causation and spread of the disease by personal infection, and it is this, I believe, that is the cause of the great increase in urban districts, and especially in London, in recent years. When one remembers the opportunities now existing for close personal contact among children in public and private schools, Sunday-schools, and private gatherings, as compared with what was the case even twenty years ago, it is not to be wondered at that such increase in diphtheria has taken place. The wonder is that it is not greater and that outbreaks such as recently occurred in the parish of Wandsworth have not been more numerous. In these outbreaks there is no doubt that in every case personal infection was the only cause in operation, although it was not in every case that such could be definitely proved. These outbreaks occurred in Wards 1 and 3 of the parish of Wandsworth, which had a population, principally working class, of 8670 and 11,817 respectively at the census of 1896. The wards are not adjacent to one another, and the outbreaks had, as far as could be ascertained, no connexion, although in both school infection was proved to have been the means of spread, and this most definitely in the outbreak in Ward 3. That school attendance is a prominent factor in the dissemination of diphtheria has long been known, and Sir R. Thorne Thorne, in his Milroy Lectures, has summarised all our knowledge of the subject. The conclusions arrived at by Sir R. Thorne Thorne are so generally known that it is unnecessary to recapitulate them, but there is one statement that, in view of the recent outbreaks in this district, is specially noteworthy. Sir R. Thorne Thorne states that "there are ample grounds for believing that the aggregation of children in elementary schools constitutes one of the conditions under which a form of disease of particular potency for spread and for death may be, so to speak, manufactured"; or, in other words, that in diphtheria there is a "progressive development of the property of infectiveness."

Before proceeding to discuss this as a cause of the virulence of the outbreaks it will be necessary to give some particulars with reference to them. In Ward 1 sporadic cases of diphtheria had occurred during 1896, 27 cases having been notified in that year at intervals of from fourteen to thirty days. Most of the cases were exceptionally mild. In January, 1897, however, 8 cases were notified with 3 deaths, 5 of the cases occurring in one family, 2 of these proving fatal. The causation of these 5 cases is important as showing a certain connexion between this outbreak and the one at Roehampton in the adjoining parish of Putney, which had occurred in the months of October and November, 1896. One of the children affected attended a school in Roehampton, at which all the children affected there were scholars, while the other four children attended the board school in Ward 1 of this parish. During the month of February 20 cases were notified with 7 deaths, and in March 17 with 2 deaths. The total number of cases in the ward was 45, 25 males and 20 females, with 12 deaths, a percentage of 26·5. These 45 cases occurred in twenty-three households; in four households 5 cases occurred in each; in six, 2 cases; and in thirteen, 1 case. In this ward there are two schools, one a board school and the other a national school, and of the twenty-three households affected the first cases occurred in thirteen households in children attending the national school, in nine the board school, and in two households the children infected had not been to any school. At first it was difficult to localise the school in which infection took place, as in a preliminary inquiry it was found that the cases occurred in both schools at varying intervals and among children who did not in school associate with one another. In the board school an examination of the cases showed that 10 attended the infant department, 3 the girls' and 2 the boys' departments. In the infant department the first three cases were members of the same family, and none of them had been in attendance at school for over seven days. The next two cases in that department did not occur for three weeks, the first on Jan. 21st and the second on Jan. 26th, but they did not attend the same class at school, although they, on entering and leaving school, passed through the same corridors. In this department all the children have a common playground. In the girls' department the cases occurred in separate classrooms. In the boys' department the first case was notified on Feb. 4th and the second on March 2nd. Attention was then directed to the national school, which was attended by a little over 100 scholars, and here, also, it was in the earlier cases difficult to say that school attendance was the sole cause of the outbreak. Five out of ten cases occurred up to Feb. 27th in which the infection was caught at school, two of these being members of the same family. These cases were notified, one on Feb. 16th, two on Feb. 18th, one on Feb. 20th, and one on Feb. 22nd. It was then thought that the outbreak had abated as far as this school was concerned, but on March 3rd three notifications were received, in one of which the first symptoms appeared on Feb. 22nd, in another on the 24th, and in the third on the 27th. On March 4th two notifications were received, in one of which the symptoms were said to have appeared on Feb. 20th, and in the second on the 27th. On March 5th four notifications were received, three of these being with respect to two children and one adult in a previously infected house, while the fourth case did not go to the day-school at all, but to the Sunday-school. All the first children infected had been in close contact in the above day-school or Sunday-school, and it was also ascertained that of the earlier cases several were in attendance on the Sunday-school, which was held partly in the same building as the day-school. The board school, although attended by over 800 scholars, was excluded as the cause of the disease, but the national school was closed on my instructions on March 5th for fourteen days, with the almost immediate effect of checking the outbreak. After that date six notifications were received, only one of these from a household not previously infected. This child had been to school on March 5th, the first symptoms appearing on the 7th. The other five were secondary cases. Out of the twenty-three households infected in only six were there any sanitary defects, and these were of a minor character. In four the connexion between the water-closet and the drains was defective.

In this outbreak it was at first difficult to arrive at a definite conclusion as to its causation, owing to delay in notification of the cases. In four of the cases no medical man was called in until some time had elapsed, and children from the infected households were meanwhile attending school. In one or two cases there was difficulty in diagnosis, as some of the attacks were mild and not well-marked, whereas others were of a severe and virulent type. The fact that the outbreak was checked by the closure of the school affords strong grounds for the belief that, at any rate in the later cases, the infection was received at school, and principally at Sunday-school, where the same control is not possible as far as overcrowding is concerned.

The outbreak in Ward 3 was of a very malignant character, and this was specially marked in the primary cases. This outbreak was limited to children attending one school, and the infection was traced to the attendance of a child suffering

Digitized by Google

from the disease at school on the afternoon of March 2nd. For some months previous to this no cases had occurred in this neighbourhood, and the school had always remained very free from diseases of an infectious nature. Inclusive of the above case, 31 notifications were received between March 6th and 18th, and 13 deaths resulted, a percentage of nearly 42. The first case which was the cause of the outbreak proved fatal, and of the 11 cases primarily infected by this 7 died. In 7 cases the first symptoms appeared on the evening of March 4th, and of those 6 died; in 4 on March 5th, with 1 death; and in 4 on March 6th, with 1 death. These 15 cases were all infected at school on March 2nd, 3rd, and 4th, and, as might have been anticipated, were the cause of other cases, not only in the same households, but in others. One monitor, a girl aged fourteen years, was infected on March 5th as on that date in school she nursed one of the previously infected cases who had turned ill, and the first symptoms appeared on March 8th. The type of disease in the early cases was more virulent, but the secondary and tertiary cases were of a milder type. In all, twenty-five households were infected, but owing to prompt diagnosis, notification, and isolation the outbreak did not last long. The disease was so virulent and the symptoms in the early stages were so definite that prompt isolation was at once carried out, with the result that in these households only two had secondary or tertiary cases. The school was closed on March 8th for twenty-one days, and after that date thirteen cases were notified, but of these four cases occurred in households previously infected. An analysis of the other nine cases showed that two in whom the first symptoms appeared on March 9th had been at school on the 5th and 8th, while the remaining seven were all ascertained to have come into direct contact with some of the previously notified cases. The last notification from this part of the district was received on March 22nd, the first symptoms having appeared on the 20th, and the outbreak subsided almost as rapidly as it had commenced. In nine of the houses where cases occurred sanitary defects were found after testing, but these, as in the outbreak in Ward 1, were of a slight character, mainly consisting of defective water-closet arrangements. In all the cases occurring in these houses a definite history of contact with a previous case was obtained. The milk-supply in all cases was the subject of careful inquiry, but no connexion between this and the outbreaks in either ward could be traced. The sanitary arrangements of the school in Ward 1 were carefully examined and the drains tested, but only a slight defect was found, this consisting of an untrapped rain-water pipe. In Ward 3 the sanitary arrangements of the school were excellent, the drains having only recently been laid under the supervision of the sanitary inspector.

A review of all the circumstances attending the three outbreaks—the one at Roehampton and the two in Wandsworth—emphasises the fact that diphtheria may show varying degrees of virulence in different outbreaks. In the Roehampton outbreak out of 30 cases reported not one proved fatal. In the first outbreak in this parish 45 cases were reported, of which 12 proved fatal, and in the second 31 cases with 13 deaths. Again, in Ward 1 of this parish diphtheria had been present, though in a mild form, during the previous year; and it is a well-known fact that virulent outbreaks are frequently preceded by a prevalence of sore-throat or of true diphtheria of a mild character. It is difficult to say definitely whether the outbreak in Ward 3 arose out of that in Ward 1. Every inquiry was made into the history of the child first affected in Ward 3, but no definite information could be obtained as to contact with any of the cases in Ward 1. It is quite within the bounds of possibility that such contact did take place, and if so it would further verify the statement made by Sir R. Thorne Thorne as to the progressive power of infectiveness of this disease. The lessons to be drawn from these and similar outbreaks are, in my opinion—that all cases of sore throat should be immediately isolated, and that when possible a bacteriological examination should be made. Immediate notification should be made to the medical officer of health, not only of cases where the symptoms are on the first examination definite, but also in all cases which are at all suspicious. These measures would ensure the exclusion of all infected children from school, and this is, in my opinion, the most important etiological factor in the dissemination of diphtheria in urban localities, and especially in the metropolis.

Wandsworth, S.W

A CASE OF APPENDICITIS WITH SOME UNUSUAL SYMPTOMS.

BY CHARLES D. GREEN, M.D. LOND., F.R.C.S. ENG.

AN ill-nourished and undersized lad, aged fifteen years, was on Sept. 27th, 1893, while employed in field work, obliged to return home on account of abdominal pain. I saw him the same evening; he gave no history of any previous bowel trouble. He had felt a little pain in the abdomen before starting for work, but went to work as usual, walking nearly two miles for the purpose. He continued at work during the morning, but was obliged to return early in the afternoon on account of increase in the pain. He had vomited once during the day. When I saw him he was lying on his back; he did not appear to be seriously ill; his abdomen was not distended, and no tenderness was elicited on examination; his tongue was clean and moist, and his bowels had been open. He had eaten some raw turnip, amongst other things, during the day; no aperient was given, but absolute rest was enjoined. The next day some tenderness was evident in the right iliac fossa. On the 29th the temperature was 101° F.; there was some exudation on the right side; the abdominal walls were rigid; there was a distinct tender spot two inches below, and one inch external to, the umbilicus, and at this spot there seemed to be a greater sense of resistance than elsewhere. The sense of resistance was, however, ill-defined and diffuse; there was no dulness on percussion. The next day (the 30th) the temperature was 102° and there was a little dulness over the tender spot; the general condition did not seem grave. On Oct. 1st and 2nd there appeared to be some amelioration; the temperature on the latter date was 100°, the tongue was moist and clean, there had been no further vomiting since the onset, and the general condition remained about the same; the signs of local exudation were more distinct. So far the case had appeared to me to have been a simple one of appendicitis, localised and threatening to suppurate, but not calling for immediate operation. On the night of the 2nd, however, a sudden and severe exacerbation of pain took place. On the 3rd the temperature was 101°, there was considerable distension of the abdomen, and severe pain referred to the right iliac region; the dulness previously noticed had disappeared. On very light percussion, however, the note seemed somewhat damped over a small area the centre of which was about the middle of a line drawn from the umbilicus to the middle of the right Poupart's ligament. There had been no vomiting. The treatment had hitherto been small doses of opium and enemata; these latter had, however, only brought away a small quantity of hard fæces, evidently from the lower bowel, and it was stated that no flatus had been passed. It was now evident that operation was called for, and it seemed to me that perforation of the appendix had taken place during the night and that if general peritonitis had not already begun the risk of its occurrence would be materially increased by moving the patient. I therefore decided to operate on the spot, although the patient was a pauper and the surroundings far from favourable. On the morning of the 3rd, chloroform having been administered, I made an incision three inches long in the right iliac region; the peritoneum was thick and vascular, and on dividing it I came upon a thickened mass which I took to be the edge of the great omentum. On separating the lower edge of this from its connexions about four ounces of foul-smelling fluid escaped; this was thin and semi-purulent, with flocculent material floating in it; no actual pus was found. The finger inserted into the wound failed to define clearly the appendix, it appeared to be curled up behind the cæcum; a mass of adherent small intestine could be felt at the upper and inner part of the cavity; the finger brought away two fæcal concretions of the size and shape of rice grains, and four other similar concretions were subsequently found in the fluid that had been evacuated. The cavity was gently irrigated with warm mercuric chloride solution (1 in 2000), the upper part of the wound closed with a silk-worm gut suture, and a rubber drainage-tube inserted. The patient rallied well from the operation, the pain was relieved, and there seemed at first every prospect of a quiet course. The temperature did not rise above 100°; the bowels, however, in spite of enemata, were not opened, no flatus was passed, and only a small lump of hard fæces, evidently from the lower

Digitized by Google

bowel, the abdomen became increasingly distended, and by the evening of the 6th this symptom had reached an alarming extent; during the night the patient became much worse and vomiting commenced. On the morning of the 7th the temperature was 97° and the condition of the patient was very alarming, and it appeared to me that there was intestinal obstruction, probably from matting together of small intestine, and that it would be necessary to open the bowel for relief. About 11 A.M., however, a considerable quantity of flatus was passed with some relief to the distension and I decided to wait; in about an hour a copious evacuation followed and all anxiety about obstruction was at an end. Except for the passage of residual contents of the large bowel, constipation had apparently been complete for ten days. During the afternoon of the same day (the 7th) a series of fits occurred, beginning with movements of the fingers of the right hand and gradually spreading to all the limbs, and followed by a period of complete unconsciousness lasting fully five minutes. During these attacks the head was turned strongly to the right and the eyeballs were turned upwards. There was no optic neuritis. On the following morning the patient appeared to be a little better, though much exhausted, but complained that he was totally blind. The pupils were widely dilated. No change was discovered in the retinæ and there was no squint. A slight fit occurred about 4 P.M. The wound was looking well and quite sweet. During these two days there were frequent alvine evacuations, and in the course of the violent convulsions the dressings became disarranged and the wound soiled with fæces. The distension of the abdomen was now completely relieved. On the night of the 8th he had a long and refreshing sleep. The amaurosis had disappeared on the 9th, and for several days afterwards the case ran an uneventful course. On the night of the 17th, however, the patient again complained of abdominal pain and his temperature went up to 101°. The wound had by this time much contracted and was looking well. The tube had been extruded on the 8th, and as there was very little discharge it had not been replaced. The temperature remained during the next two days at from 101° to 102° and the pain continued. On the 19th Mr. Ballance very kindly saw the patient and advised that a counter-opening should be made as far back as possible; this step was carried out on the 20th and a drainage-tube was carried through; irrigation was practised from behind forwards. Some troublesome oozing took place. After the operation the temperature had fallen to 99° and some considerable degree of improvement was manifested, but the patient's condition was not entirely satisfactory; there was considerable abdominal pain and the temperature did not reach the normal. On the 23rd, during irrigation, some clear fluid passed from the anus, but this did not again occur. On the 24th and 25th there was some hæmorrhage from the anterior wound and the temperature had gone up again to 102°. On the 27th there had been no further hæmorrhage, but the temperature remained high, the discharge was offensive, and the patient was evidently suffering from septic absorption; the anterior wound was therefore dilated with the finger, some septic clot was removed, the cavity was well irrigated with hot perchloride lotion, and gauze packing was substituted for the drainage-tube. In the evening the temperature was 100°; there was no pain, and the general condition had already improved. The cavity was irrigated daily with hot chlorinated soda from behind forwards, and the plug in the anterior wound was changed daily. On the 30th a small slough separated, and on the 31st six large pieces of slough were washed away, none of which could be recognised as being the appendix. From this date convalescence was uninterrupted, and when last seen (in June, 1896) the lad was in good health and had been in active work since the spring of 1894. There was some tendency to hernia through the cicatrix. With the exception of the concretions found at the first operation no fæcal matter had passed through the wound at any time.

Remarks.—This case in its protracted and stormy course, and in the extensive sloughing of false membranes that occurred, resembles that described by Mr. Stanmore Bishop in THE LANCET of Dec. 19th, 1896. I am at a loss to explain the convulsions that occurred—I suppose they were a toxic effect of the retained intestinal contents. I have, however, seen one such fit occur in a man during the course of a mild attack of appendicitis. I was inclined to attribute the sloughing in my case to some secondary septic contamination the result of puerperism and dirty surroundings, but in Mr. Bishop's case, in which the lesions must have been very similar, there were no such influences. The development of a dangerous degree of abdominal distension after an apparently satisfactory operation was, I think, a remarkable feature in my case. I do not think Mr. Moynihan, in his article in THE LANCET of Dec 26th, 1896, quite fairly represents the advice of Professor Reclus in regard to the operative treatment of these cases, for in the article on Appendicitis in the sixth volume of the "Traité de Chirurgie," edited by Reclus and Duplay, on p. 527 there occurs this passage: "Roux, ... Dennis, Reclus, Berger, sont d'avis que trente-six ou quarante-huit heures d'aggravation progressive justifient pleinement l'intervention." One other curious phenomenon I met with in what I believe to have been an appendix case is, perhaps, worth relating. In the beginning of November, 1889, a man, aged thirty-four years, had abdominal pain and fever followed by well-marked exudation in the right iliac region; his symptoms were never acute, but in the second week, when the exudation was clearly subsiding, there developed emphysema over the right abdominal wall and the back of the right thigh; this persisted some three days and was not attended by any exacerbation of symptoms; no suppuration occurred. He made a good recovery without operation. I last saw him in the early part of 1896 and there had been then no recurrence. I think there must have been in this case a minute extra-peritoneal perforation.

Upper Edmonton.

REMOVAL OF A BULLET FROM THE THIGH AFTER THREE YEARS BY THE AID OF X RAYS.

BY W. J. COLLINS, M.S., M.D., B.SC. LOND., F.R.C.S. ENG.,

SURGEON TO THE ROYAL EYE HOSPITAL AND THE LONDON TEMPERANCE HOSPITAL.

A MAN, aged forty-three years, when leaving the train at Halifax, Nova Scotia, about three years ago, was shot at by a woman carrying a revolver. The woman was a stranger to him. At the trial a plea of insanity was set up, but failed, and she is undergoing fourteen years' imprisonment. Examination at the time showed that a bullet had entered the right thigh between the great trochanter and the crest of the ilium. An attempt was made to extract it, but unsuccessfully. On Aug. 28th of this year he applied for admission under my care at the London Temperance Hospital. He was a healthy man; the cicatrix of the wound of entry was plainly visible about an inch above the right great trochanter. On the outer side of the right thigh, about midway between the great trochanter and the outer condyle, was a small abscess, evidently leading to a sinus. This had only appeared about a fortnight, and there was no

FIG. 1.

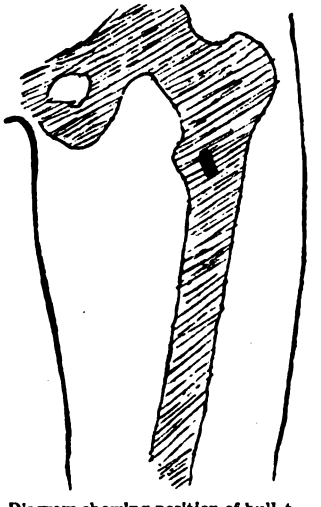

Diagram showing position of bullet as seen in skiagraph.

FIG. 2.

Facsimile of bullet.

Digitized by Google

other known cause for it than the possible effects of the presence of the alleged bullet. On Aug. 31st he was by my direction x-rayed by Messrs. Coxeter, and being satisfied from an inspection of the negative of the presence of a bullet in the neighbourhood of the femur about the level of the trochanters I determined the same day to make an attempt to extract it. It was not possible to adjust an "Esmarch" at this level. The single radiogram did not permit of predication as to the bullet being in front of, or behind, the femur. I accordingly elected to follow the sinus above mentioned as an Ariadne's thread to the object of my search. Following for some six or eight inches this sinuous track by the guidance vouchsafed by its granulation-clad walls I reached the femur at the level of the lesser trochanter. My left index finger led me to a hard-walled cavity at the back of the femur, in which I felt the end of the imprisoned bullet. I passed a Nélaton's probe over its surface, but without a very reassuring result. A pair of sequestrum forceps, however, easily facilitated the extraction of the bullet. The wound healed rapidly and he was discharged on Sept. 16th. The bullet was a conical one, three-quarters of an inch long and seven-sixteenths of an inch broad.

I have used the x rays in several other cases. In one I was led by their use to the discovery and extraction of a portion of a needle jammed into the superior tibio-fibular articulation so firmly that it required considerable force to remove it with pliers. I ought to add, by way of caution, that in another case I was assured by the radiographer that there was a needle in a boy's knee, as the boy himself alleged and as a radiogram seemed to show. I opened his knee-joint and searched in every nook of that joint and found nothing. On again submitting him to the radiographer I was assured the needle had disappeared. I am glad to say the joint was none the worse for its searching scrutiny, and the boy afterwards ran about without any pain or inconvenience. I merely cite this case to show that some caution is necessary in interpreting our newly acquired means of diagnosis. I also know of a case in which a peculiar appearance of a portion of the femur led the radiographer to infer the presence of necrosis of a considerable area of the shaft of the bone. The symptoms of the case were, however, conclusively against such a possibility. This case again leads me to the conclusion that while gratefully acknowledging the valuable addition to our methods of investigation which Professor Roentgen's discoveries have placed in our hands, it is a mistake to suppose that even in the limited region to which the new method is applicable it has reduced surgical diagnosis to the mere contemplation of pictorial effects. Radiography requires surgical insight and surgical judgment to interpret correctly the phenomena it presents us with and to direct appropriately the course of treatment to be founded thereon.

Albert-terrace, N.W.

SWINDON VICTORIA HOSPITAL.—At a meeting of the committee, held on Sept. 28th, it was reported that the total sum subscribed as the Jubilee Memorial in Swindon towards the Swindon Victoria Hospital Endowment Fund was £1847. The expenses amounted to £265, leaving a balance of £1576 to be vested in the trustees of the hospital.

THE SOCIETY FOR PHYSICAL VOICE-TRAINING.—A public meeting was held under the auspices of this society at Nottingham during Church Congress week, with the object of furthering the work amongst candidates for holy orders. Archdeacon Emery gave a brief sketch from the chair of the movement which had its origin at Nottingham, when the British Medical Association met there in 1892, and mentioned the names of Dr. Dundas Grant, Dr. Sandford, and Mr. Wyatt Wingrave as the medical pioneers. Archdeacon Emery concluded his address by recalling to his hearers the memory "of his old college friend, the late Rev. Professor D'Orsey, who had done so much for thirty years to establish a higher standard of elocution at the Universities, in Parliament, and in the Church." The honorary secretary (Miss D'Orsey, a daughter of Professor D'Orsey) reported that the work was going steadily forward, and read a letter from the secretary of the Junior Clergy Society of London asking for a medical lecturer to address the clergy at Sion College in October as a proof that laymen were waking to the facts that voice-training had its distinct medical side.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A PERSONAL EXPERIENCE OF MALIGNANT DISEASE OF THE LARYNX.

BY C. FLEMING, L.R.C.P. & S. IREL.

THE loss of so many valuable lives from cancer of the larynx, the importance of early diagnosis, and of skilled surgical interference, is my excuse (if any is needed) for bringing my own case before the readers of THE LANCET. About the end of June, 1895, my friends noticed a certain amount of change in my voice—huskiness or weakness, they said. I spoke as if I had chronic "laryngeal catarrh." I attributed it to getting heated whilst bicycling and congestion of the throat following from the inhalation of the colder air. My voice became very gradually more muffled in tone; I had no other discomfort whatsoever, no pain, no tenderness on external pressure, no swelling, no glandular trouble, no difficulty in swallowing, in fact, up to the very last I felt in perfect health. Loss, or rather a husky condition, of voice was absolutely my only symptom. In November, 1895, as matters grew worse, I consulted Dr. (now Sir Felix) Semon. After a thoroughly exhaustive examination he discovered a very small growth on my left vocal cord, no surrounding inflammatory or glandular mischief, and the character of the growth not determinable. He wished to see me again in two months' time. As I did not seem to get very much worse I am sorry to say that I delayed my next visit for nearly five months; even then there was no definite diagnosis. In May, 1896, I made my next visit. Dr. Semon again thoroughly examined my throat, and expressed a wish that I should consult Mr. Butlin; I did so, but he was also unable to come to a conclusion as to the nature of the growth. The first week in July, 1896 (or as nearly as possible twelve months from the commencement of my symptoms), I again saw Dr. Semon. At this visit he advised an operation, at least of an exploratory character, but wished to have his opinion supported by another. Accordingly, I called again on Mr. Butlin, who, without being aware of my visit to Dr. Semon, said, "If I were you I would have an operation." I made up my mind at once. It was the first inkling I had given me that the growth might be malignant and I knew that I must lose no time. I now come to a most important factor in my case—namely, the universally expressed opposition I had to encounter from friends—medical and otherwise—when I expressed my intention of submitting to an operation; in fact, I must confess to sitting down to write for an appointment with a very eminent surgeon at their earnest solicitation. Happily my better judgment, or I should say my thorough confidence, prevailed. I can now fully understand the difficulties the lay mind has to contend with before accepting the final verdict and the reason why so many valuable lives have been sacrificed through similar "friendly" advice and misguided persuasion. I placed myself unreservedly in the hands of Sir Felix Semon, and on July 21st, 1896, he performed his operation, tracheotomy, laryngotomy, and complete removal of the left vocal cord, together with a certain amount of healthy tissue. The operation lasted one and a half hours. On the fourth day I sat up for an hour; on the twelfth day I went down to Brighton for a few days before returning to my work; and at the end of a fortnight the external wound had quite healed. Since then I have had no drawback, and my voice has wonderfully improved in tone and quality. The last examination, on July 29th, 1897, disclosed a most satisfactory condition, a well-marked cicatricial ridge having formed just as Sir Felix Semon expected, and quite accounted for the improvement in voice. My age was forty-nine years last February. There is no family history of malignant disease. The following is a copy of Mr. Shattock's microscopical examination: "The sections show typical squamous-celled carcinoma in an early stage. ..... Little horny transformation has taken place. I have made also horizontal sections to see how far the removal is microscopically complete. No cells of the growth reach the divided edge."

THE GLANDULAR FEVER OF CHILDHOOD.

By G. SCOTT JACKSON, M.D. GLASG.

THE following case appears to me to be fairly typical of this disease as described by Dr. Dawson Williams,[1] and yet it presents one or two points of peculiar interest. First as to the "point of entry" of the infection. In this district at present we are passing through a well-marked epidemic of "milk infection," the sufferers presenting evident symptoms of systemic poisoning, with purging, vomiting, and high temperature, which are only relieved by the complete withholding of all milk. In several instances there are also present one or two swollen glands in the neck which I presume are caused by absorption of poison from the intestine. The diarrhœa, however, in these cases carries off the poison already present and the change of diet prevents any fresh introduction. Where such is not the case and constipation is present instead of diarrhœa the absorption is more complete and glandular fever, as in the instance I am about to relate, results. This child's symptoms were so very similar to those of others round about him suffering from the epidemic, with the exception that (1) he was constipated instead of purged, and (2) the swelling of the glands was more complete, that I cannot help thinking that there is some connexion between the two disorders. That the infection is derived from the intestine rather than from the pharynx is the view held by many responsible authorities. Secondly, as to the termination of the disorder Dr. Dawson Williams observed that this is "marked by the passage of thin greenish fæces mixed with mucus" and Dr. Charles W. Chapman[2] noticed epistaxis in four out of five cases. In my case convalescence was begun by a sudden attack of hæmaturia and by the voiding of two or three offensive stools. The temperature came down at once and improvement was fairly rapid.

The patient was a healthy child, aged three years, with good family history. He went to bed apparently well on Sept. 6th, but he awoke soon after midnight screaming and seemed to be quite delirious. He vomited once or twice and was very feverish. He was a little better on the morning of the 7th, but was hot and restless all day. After another bad night I was sent for on the 8th to find the child with a temperature of 102·8° F. and a certain amount of tenderness across the bowels, which had not been moved for two days. There was no sore throat and no marked redness of the pharynx. The next day the temperature was 103° and there was a tender swollen gland along the anterior border of the left sterno-mastoid. The bowels had been opened after a dose of castor oil, but the tongue was very coated and the child refused all food. On the 11th the whole chain of glands on the left side were enlarged and tender. The temperature was still up to 102·6° and the patient was much distressed. The right side now began to be affected and on the morning of the 14th the head seemed to be fixed by a row of hard glands on each side, the temperature reaching 103·5°. In the evening of the same day I was summoned to find that the patient had been seized with an attack of hæmaturia. The temperature, however, was lower (102°) and the child seemed easier. He had a fairly good night and the next morning, after the passage of two or three watery stools, the temperature fell to normal. Though the urine contained a trace of albumin till the 20th and the swelling of the glands did not entirely subside for some little time, the child never afterwards retrogressed, but made a complete, if somewhat tardy, recovery.

Alnwick.

A CASE OF ACUTE INTUSSUSCEPTION.

By FREDERICK BROOKE, M.R.C.S. ENG.

CASES of acute intussusception are so grave in character that notes of those in which treatment has been attended with a successful issue will probably be of interest, especially since, as appeared in a recent article by Dr. F. Holme Wiggin in the columns of THE LANCET,[1] opinions differ as to the best method of treating them.

On Aug. 29th last I was called to see a female child, eleven months old, who, the mother informed me, had suffered from constipation and until that morning had not had a motion since Aug. 27th. The motion which had just been passed was lumpy in character and was slightly streaked with blood; it was not saved for my inspection. The child was well nourished but pale, was rather sunken about the eyes, and had a somewhat anxious expression. She had occasional paroxysms of pain, but in the intervals she was bright, took notice of her surroundings, and raised herself up in her cot. There was no vomiting. The pulse was not quick, but full and regular, and the skin was dry. The appetite had fallen off. Two hours before my arrival the mother had administered a teaspoonful of castor oil. The abdomen was moderately distended and not particularly sensitive to pressure. The resonance of the colon was well marked. A provisional diagnosis of constipation associated with flatulence was made and laxatives and a carminative mixture were prescribed. At my visit about 11 A.M. on Aug. 30th the eyes were sunken and the face pale and anxious-looking. The child was in great pain, there were violent straining and tenesmus, and the buttocks were covered with blood-stained mucus which was seen to be exuding from the anus; there was frequent vomiting. On passing my forefinger into the rectum I found it almost entirely occupied by a sausage-shaped tumour round which the finger could be swept and presenting a central orifice. Pressure, however slight, on the abdomen gave rise to great pain. To effect reduction I made use of enemata of warm water combined with inversion of the patient. At the first attempt practically none of the water was retained, but as it was forcibly injected a subsequent examination showed that the tumour had receded very slightly. After a short interval another pint of water was injected slowly but forcibly, and since a certain quantity of this was retained I now had the patient inverted. Per rectum the intussusception could now only barely be reached with the tip of the forefinger. Once more the treatment was repeated, the rectum being encouraged to retain as much of the fluid as possible and inversion practised as before. A further examination failed to show any signs of the presence of the intussusception. The hips were now elevated and the child ordered to be kept perfectly quiet. On calling two hours afterwards I was informed that the patient had rested quietly, had not been sick, and was very willing to take nourishment, which was only allowed in small quantities at a time. Drop doses of tincture of opium were ordered every four hours to quiet peristalsis and the patient was allowed to suck ice. On my visit at 11 A.M. on Aug. 31st I found that the child had slept for two hours at a time and that she had pain only occasionally; the abdomen was sensitive to pressure and was moderately distended. She vomited once in the early morning and once again at 6 A.M. The patient seemed brighter and the eyes were less sunken. During the day she passed flatus several times. The resonance of the colon was well marked. At 8 P.M. I was informed that there had been no further vomiting and that the child had "talked" for the first time since her attack and shown an inclination to play. Nourishment was taken readily. There was no discharge from the bowels. On Sept. 1st the child passed an almost healthy motion in the morning, the only departure from normal being the admixture of a perceptible quantity of mucus. She was laughing and playing in the mother's arms when I made my visit. The further progress of the case presented no points of interest and there has been no return of the symptoms.

SLAUGHTER-HOUSES IN BATH.—At a meeting of the Bath Sanitary Committee, held on Oct. 4th, the sub-committee recommended that if a person or a private company would submit plans for the erection of slaughter-houses on an approved site they should be favourably entertained. This recommendation was adopted, and a resolution was passed urging the Corporate Property Committee, who own the slaughter-houses in Parson's Yard, to treat for the surrender of the lease in order to close them.

ST. BARTHOLOMEW'S HOSPITAL.

A CASE OF STREPTOCOCCUS PYÆMIA TREATED WITH ANTI-STREPTOCOCCIC SERUM.

(Under the care of Mr. BUTLIN.)

IN THE LANCET of July 10th, 1897, p. 91, we published a case of pyæmic arthritis which had been under the care of Mr. Butlin and Mr. Lockwood and in which recovery occurred after the use of anti-streptococcic serum; but in that case no bacteriological evidence of the presence of streptococci was available, and, moreover, there was no definite proof of any benefit resulting from the injections. In the following case the pus from an affected joint gave a pure culture of streptococci, but the injections seemed to be of no obvious utility and death ensued very much as if the serum had not been employed. Up to the present time no certain decision can be expressed as to the value of anti-streptococcic serum; its employment has in certain cases been followed by recovery, but not in a sufficient proportion to justify the opinion that the serum was certainly the cause of the recovery. It is therefore highly desirable that as many cases as possible should be put on record in which it has been employed intelligently and with a bacteriological examination of the case. For the notes of this case we are indebted to Mr. J. Preston Maxwell, house surgeon.

A man, aged sixty-seven years, was admitted into St. Bartholomew's Hospital on April 15th, 1897, with the following history. He had always enjoyed good health until August, 1891, when he had an attack of cellulitis of the right arm and forearm. The following December he was admitted into the hospital, and a localised abscess in the neighbourhood of the right elbow was opened. In January and again in July, 1893, he was admitted with another abscess in the same situation. No necrosed bone was found on any of the occasions, and he left the hospital in August, 1893, well, with all the incisions soundly healed. He returned to the hospital on April 15th, 1897, saying that for the past week the right elbow had been swollen and painful and that it had begun to discharge. From the middle of the forearm to the middle of the arm the limb was swollen and œdematous and the skin was red. In front of the elbow-joint was a discharging sinus, and fluctuation could be obtained over the inner surface of the ulna. Several scars of old incisions were present around the joint. The temperature was 97° F., the pulse was 96, and the respirations were 30. About an hour after admission he had a severe rigor and the temperature ran up to 104°, falling again to normal in about an hour. The same evening he was anæsthetised and the elbow explored. The sinus in front was found to lead directly into the elbow-joint, of which all the articular surfaces were bare of cartilage. The joint was washed out with a solution of biniodide of mercury (1 in 2000), and counter incisions for drainage were made. The abscess on the inner surface of the ulna was opened, and found to communicate with the joint. He passed a bad night, and his temperature gradually rose till it reached 103° at 11 A.M. on the 16th. His condition was then worse; he was drowsy, his pulse was 100, and the respirations were 30; the bowels were not open, and as he had retention of urine a catheter was passed. In the evening of the 16th he began to complain of pain and stiffness in his left shoulder-joint, which was found to be distended with fluid. He was again anæsthetised, the skin was disinfected, and a sterilised needle was introduced into the joint; pus was withdrawn, which on being cultivated yielded a pure culture of streptococci. An incision was made downwards from the point of the shoulder, the fibres of the deltoid were separated, and the joint was opened; it was washed out thoroughly with solution of biniodide of mercury (1 in 2000) and a counter opening made for drainage into the axilla. His temperature continued to rise, and at 7 A.M. on the 17th it had reached 104°. He was worse and had begun to pass his motions under him. At 6 P.M. the first injection of anti-streptococcic serum was given, 15 c.c. being injected into the right rectus abdominis muscle. At midnight 10 c.c. more were injected, and sulphate of quinine was given in doses of five grains every six hours until twenty grains had been given. On the 18th his condition was still worse; he was semi-comatose and was passing everything under him. His temperature was 102°, the pulse was 84, and the respirations were 40. He was perspiring profusely and was able to take fluids fairly well. His whole body seemed to be tender, pressure anywhere appearing to cause pain. His other joints were natural. The joints which had been opened were irrigated daily with a solution of biniodide of mercury (1 in 4000) and dressed with antiseptic gauze. At 11 A.M. a further injection of 10 c.c. of the serum was given, and at 10 30 P.M. 15 c.c. were injected. The administration of quinine was also continued. He grew steadily worse, and on the 19th he was almost comatose and could not recognise his friends. The urine and motions were passed involuntarily. The temperature varied from 100° to 104°; 10 c.c. of anti-streptococcic serum were injected at 10 30 P.M. and the dose was repeated at 11.30 P.M. He now commenced to take nourishment badly and was unable to swallow properly. During the 20th he steadily grew worse; 10 c.c. of the serum were given at 10.30 A.M., but after this the injections were stopped, as it was clear that the patient was dying. He remained unconscious till his death at 1 20 A.M. on the 21st. After death the temperature rose till it reached 105°. A post-mortem examination was not allowed, but as far as could be ascertained no result whatever had followed the injections and no rash or inflammation appeared at the sites of puncture of the hypodermic syringe.

ST. MARY'S HOSPITAL.

FIVE CASES OF INJURY TO THE HEAD.

(Under the care of Mr. H. W. PAGE.)

IN few of its departments has surgery made more advance of recent years than in the treatment of fracture of the skull and its complications. Trephining was always a perilous procedure when there was so much likelihood of a septic meningitis following the operation; but at the present time it is not accompanied by anything more than a very slight risk if due care is taken in the performance of the operation and complete asepsis is practised. C. B Nancrede has shown[1] that at the present time the mortality from trephining is less than one-seventh of that occurring in pre-antiseptic days.

CASE 1. *Abscess in frontal lobe following fracture of frontal bone.*—A little boy was admitted to the hospital early in March, 1896, with a small open wound over the right frontal eminence, from which there was said to be a great quantity of purulent discharge. It had been caused by a blow on the part some weeks before. The child had a normal temperature and seemed to be in no way ill save that he was somewhat apathetic, listless, and dull. The propriety of examining the bone was obvious, and having enlarged the wound there was found a punctured fracture, and pus welled up from within the cranium. A piece of bone was therefore removed by a quarter-inch trephine, when it was seen that the pus came from beneath the dura mater and the probe passed into a cavity in the frontal lobe. The opening into this was dilated, and thus the cavity was washed out and a small drainage-tube was inserted. The discharge ceased with striking rapidity and in a few days the boy was well. A marked change, moreover, became noticeable, in that the dull, listless, and apathetic child became bright, merry, and playful. The case, indeed, afforded a very good example of the kinds of mental disorder which have often been noted in connexion with lesions of the frontal region of the brain.

CASE 2. *Compound comminuted depressed fracture; trephining a week after the injury.*—A boy, aged ten years, was brought to the hospital on March 19th, 1897, with a history that on the 12th he had been struck by the seat of a swing on the right side of his head. There was a good deal of bleeding from a wound an inch long an inch above the tip of the auricle,

[1] Medical News, Philadelphia, 1888, p. 85.

Digitized by Google

and this having been attended to by a surgeon the lips were drawn in apposition with plaster—somewhat antiquated surgery. The boy was more or less unconscious for a few hours. On the 14th and 15th there is a vague account of twitching of his left limbs having been noticed by his mother, and he was said to have wandered. He commenced also to complain of pain in his head, and as, moreover, his temperature had begun to rise and the wound discharged and looked foul he was brought to St. Mary's Hospital. The wound was now much inflamed and the temperature was 100° F. The child was perhaps rather drowsy, but it could hardly be said that any of the symptoms were really indicative of cerebral disturbance, the state of the wound being sufficient to account for them. He was, however, promptly removed to the theatre, and under anæsthetic exploration it was at once obvious that there had been considerable injury to the bone. The wound was therefore prolonged right and left, and a semilunar flap was turned down. It was then seen that there had been an extensive horizontal fracture involving the region and following the direction of the squamous suture three inches in length from the pterion backwards. The upper part of the bone had been driven in and was so tightly wedged beneath the lower that it became necessary to make three separate trephine holes in order to raise and replace it in position. This was satisfactorily accomplished, and from the dura mater itself there was cleared some adherent stuff which looked like partially decolourised blood-clot mixed with lymph, but no pus was seen. The brain pulsated naturally. With the application of carbolic acid fomentations the wound was in three days clean and the temperature had fallen to normal, but healing took place by granulation and was somewhat slow because of the exfoliation of a piece of the outer table of the replaced bone. Never at any time were there symptoms of cerebral irritation or disturbance, and in the middle of May he left for a convalescent home. Two months later he was seen to be quite well.

CASE 3. *Compound depressed fracture; wound of the dura mater.*—A youth, aged seventeen years, was admitted to the hospital in an unconscious state on the afternoon of Dec. 18th, 1895, having been thrown from a trap, of which the end of one shaft had then been driven into the side of his head. Soon after admission he vomited blood, which had probably come from the nose. The unconsciousness then became less profound and he was able to speak. Over the left parietal eminence there was a superficial graze, and immediately above the auricle was a jagged lacerated wound which was bleeding freely. Beneath it was a deep pit, as of in-driven bone. A flap of scalp having been turned back it was seen that a circular piece of bone, the size of the end of the shaft, had been driven inwards. This involved the squamous portion of the temporal as low as the petrous. The opening having been enlarged by Hoffmann's forceps the circular piece of bone, which was really in three fragments, was easily withdrawn. There was a laceration of the dura mater, and particles of brain substance, together with fragments of dried paint from the end of the shaft, were removed in the process of cleansing the depths of the wound. The bleeding had been altogether superficial, although at one time it was feared that the source of it might be a branch of the middle meningeal. The wound was closed without drainage, remained dry, and healed at once. The pulse and state of consciousness improved after the operation, but the temperature continued to be subnormal for four days. When he left the hospital early in February he was well, his long stay having been necessitated by the treatment of old-standing discharge from both middle ears. In connexion therewith it should be said that for a few days after the accident he had slight left facial paralysis, and it was by no means certain that this was not due to fracture extending into the petrous portion of the temporal bone.

CASE 4. *Compound fracture; extensive splintering and depression of bone.*—On Nov. 22nd, 1893, a boy, aged fifteen years, fell forty feet on to a rockery in a garden beneath when cleaning windows, and was brought directly afterwards unconscious to St. Mary's Hospital. He rallied, however, soon. There were several minor injuries and a bruised wound of the scalp immediately above the right ear leading to bone which was evidently much comminuted. There was no bleeding of moment. By enlargement of the wound the fracture was seen to involve the region of the pterion, and portions of all the bones which meet at this part were found to be broken and depressed. It was necessary to trephine in two places in order to elevate, and it was then found that a portion of the squamous bone of about the size of a postage stamp had been driven in towards, and lay horizontally upon, the floor of the skull. It might easily have been overlooked. When all the parts were restored to their relative positions the deficiency of bone in the cranial wall was of a dumb-bell shape—two trephine holes with an intervening portion—and extended in the horizontal direction for two inches. The middle meningeal was intact, although lying immediately beneath the line of fracture. The soft parts were adjusted with deep and superficial sutures, and excepting that middle part of the wound which had been originally contused forthwith healed without trouble. And the boy himself, as far as his head injury was concerned, was soon quite well, so that when he left on Jan. 9th, 1894, he returned to his former master's employ. When heard of subsequently he was in the best of bodily and mental health.

CASE 5. *Fracture of base; fatal hæmorrhage from lateral sinus.*—Remarkable in more ways than one this case was certainly beyond the range of surgery, but it is worthy of note because of the several interesting features which it presented. A man, aged forty years, was picked up in a street near the hospital by a policeman who the moment before had passed him walking, but happening to look round saw him, as he thought, in a fit in the middle of the road. When admitted the man was profoundly comatose, but twitchings were noticed of the right angle of the mouth, of the right arm and leg. There was no evidence of injury and he was taken into a medical ward, the story of the policeman and his symptoms alike suggesting that this was the proper place for him. He had not been long in, however, before a distinct swelling was seen in the left temporal region, and as this somewhat rapidly increased in size Mr. Page was sent for. The dressers meanwhile began to shave his head, and when the surgeon arrived at the hospital three and a half hours after the patient's admission he was greeted with the announcement that the man had that moment died. And dead to all appearances he lay. Without a second's delay, therefore, artificial respiration was begun, and under artificial respiration, the pulse having now returned, he was moved to the theatre and proceedings were undertaken to explore. A flap having been turned down from the temporal region a horizontal fracture was seen to run right across the squamous bone and blood was issuing from it. A trephine opening was made over the middle meningeal, but this vessel was found to be whole. Blood, nevertheless, poured in volumes from between the dura mater and the bone, and seemingly came from the posterior part of the cranial cavity. Plugs of gauze failing to arrest it a second opening was made over the temporo-sphenoidal lobe, and it now became possible, although with much difficulty, to plug and arrest the bleeding, which appeared to come from the neighbourhood of the left lateral sinus, if not from this blood channel itself. Artificial respiration was now no longer necessary, but after so much terrible bleeding the pulse had become extremely feeble and the man gradually sank, at no time having aroused in the slightest degree from the profound coma in which he lay. It was found that he had been a hospital patient five years before for concussion of the brain and that he had never been quite right mentally since.

Necropsy.—At the necropsy the frontal lobes were found to be most severely and extensively lacerated, and the left hemisphere was much flattened, as by compression from recent blood extravasation. There was an extensive horizontal fracture on the left side of the skull, and a basal fracture, starting near the lambdoid suture, ran in various directions and crossed the left lateral sinus at its sigmoid curve and freely lacerated it in its course. This was the source of the hæmorrhage which was in the end controlled. There was no sign of hæmorrhage in the interior of the brain.

Remarks by Mr. PAGE.—Cases 3 and 4 may be contrasted with 1 and 2 in that in the two former the promptest treatment was brought to bear upon the injured skull and restoration to health was impeded by no untoward event, whereas in Cases 1 and 2 dangers of no inconsiderable import arose in consequence of delay. Waiting for symptoms, waiting, that is, for the mischief that gives rise to them, is happily a thing of the past. It is hardly worth while to speculate what might have been if this or that had been done differently or earlier in Case 5, for I take it that even if the lateral sinus hæmorrhage could have been stayed with greater expedition the man had undoubtedly received mortal injuries to his brain. I would direct especial attention, however, to the fact that artificial respiration was of real

Digitized by Google

service in restoring life, and in giving the opportunity of resorting to measures which in a less serious case might have been followed by success. And it is conceivable that death from compression of the brain by blood might thus be averted, when in case of unavoidable delay it would otherwise prevent resort to the only means which the surgeon has at his disposal for attempting to save life. I am indebted to my dressers, Mr. Tenison, Mr. Gardiner, Mr. Wilson, and Mr. MacCallan for the notes of these cases.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Presidential Address.—The Works of John Arderne.

A SPECIAL general meeting of this society was held on Oct. 11th, the retiring President, Mr. REGINALD HARRISON, being in the chair.

The reports of the council and treasurer were read and adopted, and showed that the society is in a flourishing condition. A vote of thanks to the retiring president and to the retiring secretary, Mr. G. R. Turner, were carried with much enthusiasm. The first ordinary meeting of the society for the present session was then constituted, the President, Dr. SANSOM, being in the chair.

The PRESIDENT delivered his inaugural address on the Investigation of Some of the Nervous Disorders of the Heart, of which the following is an abstract:—There are some variations from the normal functioning of the heart which are attended by feelings of acute pleasure. This fact has been recognised from time immemorial and has been incorporated into the language of every-day life. So we have the words in the vernacular—*hearty*, *heartfelt*, and, derived from the Latin, *cordial*, with its substantive, *cordiality*. Conversely, an aching heart is in ordinary language the expression of sorrow and depression. It is a truism to many that variations of the functioning of the heart associated with subjective feelings of pleasure or of pain are consistent with a structural integrity of the organ so far as can be determined by physical means of investigation. Perturbations of the heart's rhythm, whether in the sense of tachycardia or of arhythmia or of bradycardia, are essentially independent of any structural disease of the heart and of its valves, and are entirely due to causes involving the nervous mechanism of the cardiac reflex. In a great majority of such cases careful physical examination during life reveals no trustworthy evidence of structural disease, and in some of the few in which death has occurred, and has been followed by necropsy, no organic changes in the heart have been noted. I conclude that when structural disease of the heart has been observed in the subjects of perturbed rhythm, either the latter has been a coincidence, a superadded phenomenon, or the organic cardiac changes have been secondary to the disorder of the nerve mechanism. For instance, I have seen well-marked Graves's disease supervene upon chronic valvular disease, the result of antecedent rheumatic endocarditis; and I have observed dilatation of the heart with mitral incompetence to occur in the course of Graves's disease when there has been no reason to suspect any intercurrent malady. In the latter case I have found that the signs of structural disease of the heart have borne no proportion to the degree of cardiac tumult. The subject of a very rapid heart (from 120 to 160, such rate being manifested for many months) may never show signs of cardiac dilatation or of structural change, whilst one in whom there is only a moderate tachycardia (100 and under) may manifest the advent of undoubted dilatation of the left ventricle with valvular incompetence. It is therefore necessary in every case that in addition to the employment of the ordinary method of physical diagnosis for the discovery of organic changes within the heart there should be a careful investigation of the nervous system, more especially in its relation with the cardiac reflex. On this point I propose to suggest a scheme of examination and to offer a few hints. It will of course be understood that what I propound must of necessity be brief and incomplete. In the first place I would urge the importance of keeping the patient who is to be examined as tranquil as possible. I dare suggest that in some instances it is probable (in the cases of candidates for life assurance, for example) that a life has been embittered because the physical examination has been conducted on a subject in a state of abnormal excitement, and a systolic murmur at or near the apex has been wrongly interpreted as the index of an organic disease. I suggest, therefore, that the examination should be commenced when the patient is in the sitting position, the ordinary clothing not being removed. Amongst the most important are the signs observed by inspection of the eyes and eyelids. Any protuberance of the eyeball will, of course, be observed and its relation with the condition of the thyroid and the rate of the heart's pulsation recorded. Any retraction of the upper eyelids towards the margin of the orbit must be noted, for this is a sign of considerable importance. It often exaggerates the prominence of a bulging globe and sometimes it produces the semblances of an exophthalmos when there is really no prominence of the globe. Another sign is observed in regard to the upper eyelids in many cases of tachycardia. When the patient has been told to close the eyelids gently the upper lid has manifested a very marked and unusual tremor. This sign may be observed in the early stages and also in the recovering stages of Graves's disease. Von Graefe's sign and Dalrymple's (eyelid) retraction often co-exist, but the one may be observed without the other. In some cases the normal balance of the muscles of the globe is somewhat perverted, so that one eye appears to be on a lower level than the other.[1] I have also noted in some instances a decided inequality of the pupils—of course, unexplained by organic causes—which become restored to the normal when the other disorders of function ceased. When these signs exist, especially in combination, I think they have an important significance. In the great majority of cases they are associated with heart disturbance or heart distress. The most frequent form of disorder is tachycardia, the rapid heart, persistent or paroxysmal. This has long been recognised; the association of the eye and eyelid phenomena with Graves's disease, of which tachycardia is so marked a feature, has been fully acknowledged. Less frequently the association is with extreme irregularity of the heart's action; and such irregularity, rather than rapidity, I have found in some cases of typical Graves's disease. I have observed well-marked von Graefe's sign in a man, aged forty-nine years whose pulse was only 68, but showed very marked irregularity, and in whom there was much subjective heart distress. In some of the cases in which I have observed the signs noted there were great variations of rate in the heart-beat, a state which may perhaps be termed irritable heart—for instance, in a man aged forty-eight years, manifesting slight exophthalmos and inequality of pupils, the heart-rate 76 in the sitting position, 84 in the standing, and then a sudden rise (without any evidence of discomfort) to 114. In other cases, though there have been no perversions of rate and rhythm of the heart to be noted, the patients who have shown well-marked eye and eyeball signs have manifested symptoms of distress referred to the heart. It is no doubt correct that well-marked eyelid phenomena may occur (though rarely) in those who show no cardiac signs or symptoms. Sharkey found von Graefe's sign in 12 out of 613 cases of all disease in his out-patient room. Dalrymple's sign has been recorded as frequently seen in neurotic and hysterical subjects. In many of these, however, it is probable that subjective distress at least or else deviations of rhythm occurred. I have seen well-marked von Graefe's sign in a young man addicted to alcohol and in an old woman with emphysema, both of whom manifested heart symptoms. Nevertheless, I cannot doubt that the signs I have mentioned are of considerable practical significance, for they indicate very strongly the probability that the patient who manifests them will present signs of disorder or distress of the heart. It is important that the auditory mechanism and the naso-pharyngeal tract be explored, for from data which I have already published[2] I have convinced myself that irregularity of the heart is sometimes the result of disease of these organs. The pulse at the wrist should be carefully explored by palpation and its lessons supplemented and controlled by a determination of the rate and character of the heart's pulsations as determined by auscultation. Such auscultations should at first be practised when the patient is sitting quietly,

Digitized by Google

the clothing as yet unremoved. Much valuable evidence, notably the accentuation of the second sound in its predominance in the aortic or pulmonic area, is obtained by this preliminary method of auscultation. The existence and site of muscular tremors should be observed and noted. If fine tremors of the muscles of the trunk are present they suggest a disorder of the nervous mechanism of the heart of the nature of Graves's disease. The clothing being removed the chest is, of course, to be examined by the ordinary means of physical diagnosis. In regard to the nervous disorders of the heart the most important points are the determination and the significance of dilatation of the heart and the characters and diagnostic indications of a systolic murmur heard at or near the apex. Extreme dilatation of the heart may occur from causes affecting the nervous elements, such as neuritis of the vagi, and yet the normal conditions may return in the course of a fortnight. The bulk of the heart in some cases varies considerably in the course of twenty-four hours. Hutler brought evidence to show that in the normal heart there are rhythmic diurnal variations in volume. A systolic murmur heard at or near the apex of the heart is sometimes erroneously interpreted as the index of structural disease. It may certainly be entirely independent thereof and only an indication of nervous disorder. In such cases it is of the first importance to determine whether or no there are persistent changes in the bulk of the various chambers or in the sounds which indicate overstrain in the circuits. A loud second sound over the pulmonary artery means structural disease. On the other hand in the case of a systolic apical murmur due to neurosis, the heart is not dilated, and in the great majority of cases is smaller than the normal. A systolic murmur which is independent of structural disease seldom attains its maximum audibility at the exact apex, but slightly to the right, to the left, or above this point. It is usually soft and does not replace the first sound. It does not occupy the whole, but a middle period of the systole (it is meso-systolic). It is much influenced by the movements of respiration. As a rule it is intensified both during expiration and respiration (especially the latter), but it often becomes inaudible at the end of an expiration. If, therefore, rhythmical *crescendo* and *diminuendo* in the sound of the murmur are heard during the respiratory acts the murmur is probably not due to organic change. It is important that auscultation should be practised, not only in the erect or sitting, but also in the recumbent position of the patient. Very frequently a murmur is very audible in the recumbent position, but disappears when the sitting or erect position is assumed. In such case a confident opinion may be given that there is no structural disease. In a minority of cases the rule is reversed, and a murmur which is not detected in a patient in the recumbent position becomes audible when the erect or sitting posture is assumed. Potain has made a most valuable and elaborate study of these which he calls cardio-pulmonary murmurs. He believes them to be due to causes external to the heart. When the heart is distended in diastole certain portions of the adjoining lung are pressed against the thoracic wall and the air is squeezed out of them, when there comes the systolic recession; provided always the muscular contraction is accomplished rapidly the comparatively airless tongue of pulmonary tissue becomes quickly inflated, and this sudden inflation causes the sound. The mechanism reverts for its determining cause to the nervous elements. There must be an abnormal suddenness of ventricular contraction, and for the establishing of the validity of the theory it may persist for months and even for years. With the highest appreciation of the conscientious and elaborate researches of Potain, I think that a more probable explanation of the murmur is to be found in a derangement of the nervous mechanism of the cardiac systole. The ventricular systole is a complex act—a correlated sequence of muscular contractions, as shown by the researches of Roy and Adami, of Ludwig and Hesse. It is not difficult to realise that these may be disturbed and may continue so disarranged for protracted periods, the effect of such disarrangement being a slight mitral reflex, harmless and transitory, or abnormal vibration communicated to certain portions of the structure. Whatever the proximate cause the ultimate cause is a disturbance of the nervous mechanism of the heart. My object has been to urge the importance of an investigation into the nervous condition of the heart, which should go *pari passu* with the use of the ordinary means of physical diagnosis.

Mr. WILLIAM ANDERSON read a paper on John Arderne and his Time (which will appear in full in THE LANCET shortly). He said that the hero of his communication was born in 1307, and was a contemporary of Chaucer, Wycliffe, Froissart, Petrarch, and the great French surgeon, Guy de Chauliac. He practised at Newark, in Nottinghamshire, from 1349 (the year of the Black Death) to 1370, when he settled in London and published some twenty essays in Latin on the treatment of various medical and surgical complaints. He owed nothing to his predecessors in England, where surgical practice was almost entirely in the hands of the illiterate and unskilful. His writings show him to have been well acquainted with the French and Italian writings of the time, and he appears to have been acquainted with the writings of Galen and Hippocrates. Surgery in his day was held in extremely low repute. The regular physicians looked on surgery as beneath their notice and its practice fell into the hands of:—1. Masters of surgery who probably had some slight scholastic training—a class to which Arderne himself probably belonged. 2. The barber surgeons, who had inherited the manual functions of the erstwhile monkish physicians, who were now prohibited by Papal decrees from practising. Neither the masters nor the barbers appear to have done more serious operations than phlebotomy, opening of abscesses, and extraction of teeth. They had no knowledge of how to arrest hæmorrhage, and charms and incantations formed a large part of the treatment. 3. The "specialists," who were chiefly foreign, and native itinerant bone-setters, lithotomists, and others. 4. Amateurs, mostly charitable ladies, with their simples, who probably did no more harm than the regular fraternity. There are twenty-two Arderne manuscripts in the British Museum, most of them fully illustrated, particularly with drawings of the plants which he recommends as drugs. The only operations which he describes fully are those for fistula and for cutting stones from the urethra. But mention is made of a special instrument for crushing a vesical calculus. In his preface to one of his essays, "On the Manner of the Leech," he gives much shrewd advice as to the deportment and private life of a surgeon, coupled with practical hints as to asking for a sufficient fee, giving a guarded if not wily prognosis, &c. His directions for the operative treatment of fistula *in ano* are greatly in advance of what is found in subsequent English writings till we come to the time of Richard Wiseman, although there is little that is in advance of the Greek methods. He could not, however, free himself entirely from the superstitious ideas of his predecessors, teaching, for example, that operations about the anus must not be performed when the moon is in Scorpio, Libra, or Sagittarius, "because these signs token the part in question," and that hæmorrhoids and menstruation are provoked by phlebotomy of the internal saphenous vein; while blood-letting from the external vein has the exactly opposite effect. The external applications which he chiefly employed were arsenic, verdigris, alum, &c., and oily preparations made from various flowers; but there are few of the loathsome preparations which disgrace the materia medica of later times. Of internal medicines, the two which he most commends depend chiefly on opium for their activity. Altogether, although he does not inaugurate a new era he shows both scholarship and capacity far in advance of his contemporaries, and succeeded in raising his profession in the world's esteem.

CLINICAL SOCIETY OF LONDON.

President's Address.—Loreta's Operation for Stricture of the Pylorus. — Cerebral Sinus Thrombosis. — Impaction of Tooth-plate in the Œsophagus.

THE first meeting of the session was held on Oct. 8th, the President, Mr. LANGTON, being in the chair.

The PRESIDENT thanked the members for the honour that they had done him in electing him to the chair, which he had formerly filled temporarily when a vacancy was caused by the death of Mr. Hulke. Alluding to the prospects of the society he pointed out that although its prosperity, as evidenced by the number of members and the state of its finances, was more satisfactory than it had ever been, there were difficulties to contend with. They had to fear the indifference of members as well as the rivalry of younger societies. He pointed out how thoroughly the society had justified its existence, and referred in particular to the important discussions during last session on the operative treatment of disease of the appendix and to the report of the

Digitized by Google

committee on myxœdema, which had not only enlightened the profession as to the pathology of the disease, but had led to the discovery of a means of combating the disease which had proved applicable in a number of other morbid conditions. He presented the new volume of the Transactions to the society, congratulating the secretaries on the punctuality with which they had prepared it, and announced that the new index to the first thirty volumes was almost ready and was, he believed, the best index of the kind in existence. In conclusion, he announced his intention of deferring the usual inaugural address until the first meeting of next session.

Dr. WM. HENRY WHITE and the PRESIDENT related a case in which Loreta's operation was performed for the relief of Stricture of the Pylorus. The patient was a man, aged thirty-two years, who had had good health till he was twenty-eight years of age, when he had typhoid fever. For three or four years he had had severe gastric pain increased by solid food and relieved by vomiting, and during the last few months before he came under observation he had emaciated rapidly, and he had become almost unable to retain food at all. In July, 1893, when Dr. White saw him, he weighed only 7st. 3½lb. He was very restless, and there was considerable pain, especially after food. The abdomen was retracted, and on deep palpation an indefinite swelling could be detected in the neighbourhood of the pylorus. As the emaciation and vomiting continued in spite of treatment Dr. White asked Mr. Langton to see him with a view to surgical assistance. It was agreed that the duration of the symptoms rendered malignant stricture unlikely, and the consent of the patient was obtained to the operation of laparotomy in order if possible to perform dilatation of the pylorus. A few adhesions present were easily separated, and the pylorus was found to be very dense and hard. An opening was made into the stomach, and the pyloric orifice proved to be so tightly stenosed that it only admitted a No. 1 catheter. Larger and larger instruments were cautiously passed through the pylorus until at length two fingers could be introduced. The wound in the stomach was then closed with Lembert's sutures. The patient made an uninterrupted recovery, and was able to take solid food on the twelfth day. He was seen three years after operation in perfect health, able to eat anything, and weighing 11 st. 7 lb. The publication of the case had been delayed until it could be certain that the relief of symptoms was permanent — Mr. PEARCE GOULD congratulated Dr. White and Mr. Langton on the success of the operation. He remarked that Loreta's operation had never become popular in this country, pyloroplasty being in much greater favour. Recently at a congress of German surgeons pyloroplasty, or sometimes anastomosis between the stomach and small intestine, had been recommended even when the ulceration was elsewhere than at the pylorus, so as to allow of ready escape of the gastric contents. The objection to Loreta's operation was that there was a tendency for the symptoms to return. He had published several years ago a case in which he performed Loreta's operation for a simple stricture of the pylorus with immediate relief to the patient's symptoms. The subsequent history of that case was very instructive. Some months later the symptoms recurred, and on exploration extensive adhesions were found between the pylorus and the liver, which he broke down, and there was again immediate but temporary relief. Twelve months later he was again compelled to operate and found still more extensive adhesions. At the present time the symptoms had again returned and the patient was in as miserable a condition as before the first operation.—The PRESIDENT said that the operation in this case had been done four years ago before pyloroplasty had come into vogue. He felt certain now that that was the best operation for cases of this description. In such a case as Mr. Gould's, where there was recurrence, he thought that the best course would be to perform gastro-enterostomy. Judging, however, from the statistics of his own hospital the risks of this operation were very great.

Dr. A. G. PHEAR read an account of a case of Cerebral Sinus Thrombosis occurring in a child aged seven years. The onset of the symptoms was abrupt, the child, after calling out loudly, immediately becoming unconscious, and not fully regaining consciousness throughout her illness, of which the duration was twenty days. There was no evidence of middle-ear disease, nor could an account be obtained of antecedent diarrhœa, or of any acute specific fever except measles at the age of five years that there must have been previous ill-health was, however, indicated by the contracted state of the kidneys discovered at the necropsy. The main features of the case consisted of prolonged unconsciousness, with great restlessness and irritability, the child often tossing her limbs about with considerable violence, crying out, and actively resenting interference, though in other respects insensible to her surroundings and passing urine and fæces under her. There were no convulsions or vomiting. The only sign of motor irritation was rigidity of the posterior neck muscles and of the abdomen; the rigidity was persistent, the head being retracted and the abdomen at times hollowed. There was for a short time a slight divergent strabismus. The pupils were equal. No satisfactory view of the fundus was obtained. There was no discharge from the ear, no epistaxis, and no localised œdema about the root of the nose or elsewhere. The knee-jerks were exaggerated; no ankle clonus was obtained. The temperature was raised at the beginning and end of the illness; it gradually fell from 104° F. at the onset to 99°; there was then a period of eight days during which the temperature was normal; later it again rose to 102·4°. Cheyne-Stokes respiration was noted twice; on the first occasion groups of two or three forcible respirations were separated by a prolonged pause; the second occasion was characterised by a gradual rise and fall in the amplitude of respiration. Respiratory symptoms were at no time urgent. Towards the end of the illness diarrhœa set in; with this the strength rapidly failed and the child died from exhaustion. At the necropsy the whole of the superior longitudinal sinus was found to be blocked with partly decolourised adherent and ante-mortem clot, extending for about an inch into the tributory veins on either side. The left lateral sinus was distended with similar clot, continued into the internal jugular vein, the whole length of which was occupied with ante-mortem clot, extending for a short distance into the left subclavian vein. The left innominate vein contained dark post-mortem clot. There was no œdema or softening of the brain substance; the ventricles contained no excess of fluid. There was no evidence of meningitis. Both middle ears were healthy. The left branch of the pulmonary artery was completely blocked with decolourised and adherent clot, extending into its ramifications. The left lung was for the most part solid, of a deep plum-colour and firm consistence; it was in places broken down into a brownish semi-liquid material; there were also small areas in the lung substance, pale and tough, apparently of cicatrised tissue. The left ventricle of the heart was hypertrophied. The kidneys were shrunken, especially the left kidney, which weighed only 1 oz. The capsule stripped with difficulty, and the kidney substance was pale, opaque, and very tough.—Dr. KINGSTON FOWLER referred to a specimen of the same nature from an adult in the Middlesex Hospital Museum in which the longitudinal sinus and its tributary veins were blocked. In this case the whole of the centrum ovale and the cortex were studded with punctiform hæmorrhages, and Dr. Phear's case, he thought, was exceptional in the absence of such hæmorrhages. Great difficulty was found in making a diagnosis at an early stage, as many of the cases occurred in anæmic girls, and the mental condition often strongly suggested hysteria. The condition of the lung was interesting. It would be noticed that infarction was found only in the left lung, and that it was the left pulmonary artery only that was thrombosed, confirming the view (which has been opposed by some pathologists) that infarcts may be due to thrombosis of the pulmonary artery.—Dr. BERTRAM ABRAHAMS said that he was not aware that any of these cases had been previously attributed to renal disease. The causes were to be arranged in three groups: (1) septic, affecting especially the lateral sinus; (2) traumatic, as in a case quoted in which thrombosis of the cavernous sinus followed fracture of the base of the skull; and (3) a depraved condition of the blood such as occurred in anæmia, &c. It seemed to him that in this case the disease might possibly have been septic as there was breaking down of the pulmonary infarcts, and he inquired if any bacteriological examination was made of the thrombi. —Dr. PHEAR, in reply, agreed that it was usual to find hæmorrhages, even so extensive as to lead to softening, but they were searched for in vain in this case. The question of hysteria had been raised, but the sustained pyrexia excluded it. He thought that pulmonary infarcts in a slowly dying unconscious patient were very likely to become contaminated with retained septic mucus from the higher respiratory passages, and he would therefore hesitate to regard the

Digitized by Google

disease as originally septic, because septic changes were found in the infarcts. In his Goulstonian lectures Dr. Newton Pitt had referred to renal disease as having been associated with venous thrombosis in several cases.

Mr. G. H. MAKINS related a case of Œsophagotomy for the removal of an impacted tooth-plate in which cellular emphysema developed in the tissues of the neck although the pleura was not injured. The patient was a man, aged forty-eight years, and the plate, which was swallowed during sleep, had been in the gullet for four days. The position of the plate having been determined by the use of the fluorescent screen the classical operation was done at the root of the neck on the left side. During its performance dilatation of the lower angle of the wound was followed by the distension of the loose tissue of the carotid sheath with air. Beyond this when the œsophagus was opened air passed in and out of the tube with the movements of respiration, and as primary union of the wound did not occur, in consequence of the ulcerated condition of the gullet, gastric juice apparently found its way upwards, with the result of somewhat retarding the permanent closure of the wound. The first point was explained by the opening up of the subpleural tissue of the mediastinum and the entrance of air from without, which on expiration was driven into the tissues of the neck, and the second point by the patent condition of the gullet noted at the time of operation.—The PRESIDENT said that he had seen many instances in which foreign bodies after being swallowed had been arrested at the level of the cricoid cartilage. He recalled one case under the care of the late Sir William Savory in which a dental plate had been swallowed five or six days before. There was a good deal of emphysema in the neck, and diffuse cellulitis set up by the ulceration of the œsophagus. The patient died from acute blood poisoning, as in his experience most of these cases did if the plate had been impacted more than a day or two. He had seen air pass down into the anterior mediastinum outside the pleura when glands were being dissected out at the root of the neck, but the cases all did well. — Mr. PEARCE GOULD recalled a case at the Middlesex Hospital in which a tooth-plate had ulcerated through the pharynx and caused death from blood poisoning. It was most important to remember the extreme mortality connected with these cases. He remarked that Mr. Makins's case illustrated the extreme value of the Roentgen rays in detecting not only the position but the existence of the foreign body, as it was often most difficult to determine whether or not there was a foreign body in the œsophagus. He was aware of one case in which a man was supposed to have swallowed a tooth-plate. A probang was passed and the plate was supposed to have passed down into the stomach, but a subsequent examination showed that it had slipped up behind the soft palate. In Mr. Makins's case the escape of gastric juice was a more remarkable complication than the emphysema, and he inquired whether it was acid or contained peptones.—Mr. MAKINS, in reply, said that he thought that the œsophagus was rarely found collapsed, at any rate in adults; and in flatulent conditions he thought that the cardiac orifice of the stomach might be patulous, and it was in this way that he explained the escape of gastric juice in his case. Unfortunately no attempt was made to analyse the fluid which escaped until very small quantities were available, but the discharge had exactly the appearance of that which escapes from gastric fistulæ.

OBSTETRICAL SOCIETY OF LONDON.

The Management of True and False Capsules in Ovariotomy.—Exhibition of Specimens.

A MEETING of this society was held on Oct. 6th, Dr. C. J. CULLINGWORTH, President, being in the chair.

Mr. DORAN read a paper on the Management of True and False Capsules in Ovariotomy. He distinguished a false capsule formed of mesentery, omentum, or inflammatory deposit (Pawlik), a true anatomical capsule, which consisted of the mesosalpinx alone, and a false anatomical capsule, where the lower part of the broad ligament, the parietal peritoneum, or the parametrium was involved. The management of the first variety was simply a question of breaking down adhesions; the treatment of the second and third was a less simple matter. Mr. Doran discussed when a capsule should be cut away, when it should be let fall into the pelvis, and when it should be stitched to the lower end of the abdominal wound and drained. The first course should always be followed, if possible, when the capsule was healthy. The second was necessary when the base of the capsule was too broad to be made into a pedicle, or wherever for any other reasons no pedicle could be formed, the tissue of the capsule being healthy, and hæmorrhage under control. Fixation of the capsule and drainage were needed when hæmorrhage under similar conditions was hard to control, and in all cases where the capsule showed advanced inflammatory changes associated with suppuration of the tumour. In the latter condition oozing of serum increased the danger of septic infection. A case was related where there was free general oozing from the capsule of a large suppurating cyst. The capsule was therefore fixed to the parietes and plugged with sterilised iodoform gauze, which was removed on the third day. Thus hæmorrhage was stopped and sepsis averted. Mr. Doran discussed the advantages and dangers of iodoform plugs. He also dwelt on the prejudice of many surgeons against the practice of fixing the capsule to the wound. The danger of strangulation from a loop of intestine slipping beneath the capsule was theoretical.—Dr. EDEN asked for a fuller explanation of the difference between the true and the false anatomical capsules. A pediculated broad ligament cyst opened up the mesosalpinx, but not the lower part of the broad ligament, which remained as the pedicle, and its capsule would therefore be, according to Mr. Doran, a true anatomical capsule. But many broad ligament cysts burrowed right down into the floor of the pelvis and possessed no pedicle. According to Mr. Doran's classification the capsule of such a cyst would be true in its upper part and false in its lower part.—Dr. HERMAN thought that Mr. Doran had completely disposed of the theoretical objection to stitching the capsule to the wound. — Dr. HERBERT SPENCER agreed with all the main points of the paper, but did not think that intestinal obstruction from adhesion of intestine to the stump in ovariotomy was a rare occurrence. These cases did not go to special hospitals, but the surgeons attached to general hospitals knew that this accident was far from being a rare cause of intestinal obstruction. Cases in which the intact sac could be stitched to the abdominal wall did well with the drainage-tube, but cases in which the sac had been torn or which could not be fixed to the wound and suppurative cases should be treated by gauze drainage. He had employed iodoform gauze for the last four years with very satisfactory results. In the last three years he had only once at a laparotomy used a drainage-tube, and then it was unnecessary. He thought there was in gauze an excellent means of checking hæmorrhage, averting sepsis, and blocking out intestines from torn capsules and infected areas.—Dr. EWEN MACLEAN remarked that in addition to those mentioned in Mr. Doran's paper an ovarian tumour developed within and distending a complete ovarian sac would present a true anatomical capsule of peritoneum which did not involve either the mesosalpinx or the lower portion of the broad ligament.—After remarks by Dr. DRUMMOND ROBINSON, Mr. BUTLER-SMYTHE congratulated Mr. Doran on having introduced such an interesting discussion. His usual practice with regard to the treatment of capsules was as follows. All ordinary thin capsules would be tied and dropped into the pelvis. Where portions of the cyst wall were unavoidably left attached to the capsule, rendering it thick and likely to suppurate, the capsule would be stitched in the lower end of the wound and a glass tube inserted. In those rare cases where the broad ligaments had been enormously separated, and where adhesions had been formed high up in the abdomen previously to the enucleation of the tumour, and where a large bleeding surface was left exposed, the cavity would be plugged with iodoform gauze, which would be left in for three or four days. He had frequently seen cases of iodoform poisoning, and the first symptoms usually appeared about the fourth day and were unmistakable—rapid pulse, sudden rise of temperature, headache, giddiness, and, in severe cases, vomiting.—The PRESIDENT expressed a general concurrence with the views advocated in the paper. With regard to gauze packing he had not had a large personal experience. The removal of the gauze was so formidable a matter and was apt to produce so much distress, both bodily and mental, in the patient that he had never had recourse to it unless he was compelled. At the same time he recognised its immense value in certain cases—as, for instance, in hæmorrhage from vessels to which it was impossible to apply the ligature owing to their lying so deeply in the pelvis.—Mr. DORAN

Digitized by Google

observed, in reply, that he had discussed the anatomy of the subject at length in his article on Capsules, False and Real, in Ovariotomy, with Notes of Six Cases.[1] The complicated form of tumour, of which the President and Dr. Eden had reported cases, was Pawlik's cyst, where the broad ligament was not invaded by the new growth, but was adherent to it and stretched over its surface, the false capsule being completed by adherent omentum or mesentery. He was interested in Dr. Spencer's remarks on the frequency of intestinal obstruction caused by an old ovarian pedicle. He would like to know whether in most of these cases the raw surface of the pedicle had been left exposed or sewn over. He made a necropsy many years since on a case of obstruction where the operator had closed the raw surface by suture as a precaution against the very complication that occurred. He used the drainage-tube much less now than formerly. But he found that patients did not object to it, whilst he agreed with the President that packing and abstracting iodoform gauze often gave them great annoyance. He maintained that a pulse of 144 or 156 in a case where Mikulicz's treatment was adopted all other symptoms being favourable clearly signified iodoform poisoning. In reference to Mr. Butler-Smythe's remarks he referred to a case where he removed a large cystic myoma of the uterus. The pedicle fixed by the serre-nœud was hard to keep dry, so it was freely treated with tannin and iodoform powder. The pulse became very rapid and did not fall until the powder was discontinued.

The following specimens were exhibited:—

Dr. MCCANN: Sarcoma of the Cervix Uteri.

Dr. ROBERT WISE: (1) Abortion Sac, with hæmorrhage into the fœtal membranes; and (2) Pregnant Horn from the uterus of a cat.

Dr. JOHN PHILLIPS: Ruptured Uterus, treated by intra-peritoneal hysterectomy. The patient was in the sixth month of pregnancy and the breech presented. All attempts at artificial extraction under an anæsthetic failed. Rupture occurred during the passage of the vertex. The laceration extended from the fundus to the level of the internal os uteri on the left side. On opening the abdomen several ounces of fluid blood escaped, the uterine arteries were tied, and the torn uterus was removed. The pedicle was treated intra-peritoneally. The patient when last heard of, forty-eight hours after operation, was doing well.

Remarks were made by the PRESIDENT, Dr. GRIFFITH, Dr. HERMAN, Dr. HEYWOOD SMITH, Dr. SPENCER, and Mr. DORAN.

Reviews and Notices of Books.

Clinical Methods: a Guide to the Practical Study of Medicine. By ROBERT HUTCHISON, M.D., M.R.C.P., Demonstrator in Physiology, London Hospital Medical College; and HARRY RAINY, M.A., F.R.C.P. Edin., F.R.S. Edin., University Tutor in Clinical Medicine, Royal Infirmary, Edinburgh. Messrs. Cassell and Co. 1897. Pp. 552. Price 9*s*.

THERE are so many and such excellent manuals on the same lines as this volume that it seems at first that there is no room for another. And yet we have very little doubt that this book will rapidly win for itself a large measure of success. It is fresh, terse, thoroughly up to date, and obviously the result of much practical experience in teaching on the part of both authors. An abundance of good material is crowded into the volume and the standard of accuracy maintained is very high. The first chapter, on the Method of Taking a History and the Way to Start Investigating a Case, could not be better done. Chapter II. treats of General Conditions and Appearances and is necessarily somewhat sketchy, but the student who assimilates it will have learnt a good deal. The Alimentary System and Abdomen occupy the third chapter, which is divided into six sections: mouth, pharynx, and œsophagus; abdomen; stomach; chemical investigation of stomach contents; examination of vomit; and examination of fæces. Each of these is thoroughly and fully treated, and anyone should easily be able to carry out from the descriptions the methods advised; these have been selected with much judgment. The diagrams of viscera modified from Luschka are very clear and good. The fourth chapter, on the Circulation, covers 83 pages, and is very detailed and yet very concise. The illustrations are simple and easily understood, and the text admirable. The method of percussion is thus described to a beginner: "The stroke should be delivered from the wrist and finger-joints, not from the elbow, and the percussing finger should be so bent that when the blow is delivered its terminal phalanx is at right angles to the metacarpal bone and strikes the pleximeter perpendicularly. Whenever the blow has been given the striking finger must be raised lest it should impair the vibrations it has excited, just as the hammers of a piano fall back from the wires as soon as they have been struck." Some exception may be taken to the cardinal rule the authors lay down that "in defining the boundaries between resonant and non-resonant or less resonant organs, the percussion should invariably be performed from the former towards the latter." In many, perhaps in most, cases it is wise to train the beginner to adopt both methods and to work both ways, from resonant to non-resonant and *vice versâ*. The authors adopt the more usual explanation of the presystolic murmur, and throughout are very safe to follow. To show that they are well up to date there is even a reference to Hill and Barnard's new sphygmometer, the account of which has only been published within a very short time. The clinical examination of the blood is dealt with adequately in the fifth chapter; it is short—twenty-seven pages. Methods of preparing and staining films and precise directions for mixing the stains are given. A very good coloured explanatory plate should be of great help. The sixth chapter, on Respiration, renders as intelligible as can be the various terms employed, and will be particularly useful for making more widely known Dr. Wyllie's symbols for the different abnormalities of sound, which can easily be represented on charts. In the chapter on Urine nothing is too simple or too complex to be omitted. The quantities of urine normally passed by children of various ages (from some data furnished by Dr. Still) represent a small useful point not generally referred to. The accounts of all the quantitative testings will prove refreshingly clear to those who have a horror of figures. The detection of albumins and nucleo-albumins, and the many pitfalls in testing for sugar, are lucidly described, and there is even a paragraph about Pentosuria which should satisfy the most exacting. The eighth chapter, on the Skin, is rather short, and will bear re-casting in a new edition. The Nervous System (Chapter IX.) occupies nearly 100 pages, well illustrated by old friends and new. As a whole, it is a sound introduction to the fascinations of neurology. Perhaps it is not quite adequate nowadays to say "if the upper neuron suffers damage in any of its parts the restraint on the lower neuron is diminished, the tone of the muscles is raised, and, as a consequence, what are known as the 'tendon reflexes' of the muscles become exaggerated" (p. 364). However, the authors qualify this later by reference (p. 435) to the well-known fact that in complete transverse lesions of the cord the deep reflexes below the level of injury are not exaggerated, but disappear. The description of the systematic examination of a nervous case is excellent. Chapter X., on the Eye, Ear, Nose, and Throat, and Chapter XI., on the Locomotor System, contain much that is useful, but are necessarily somewhat brief. There is a good short chapter (Chapter XI.) on the Clinical Examination of Children, and the main points of difference between the examination of a child and an adult are well brought out. The last two chapters are on the Examination of Pathological Fluid and Chemical Bacteriology; both are full of

information, and the latter gives the simplest and most precise account of Widal's test we have yet seen.

Dictionary of National Biography. Edited by SIDNEY LEE. Vol. XLIX. Robinson—Russell. London: Smith, Elder, and Co. 1897. Pp. 496. Price 15*s*.

THE most extensively-known name in the present volume of the Dictionary is undoubtedly that of the Rothschild family, the rise of which is traced from Meyer Amschel Nathan Rothschild, of Frankfurt-am-Main, who was born about 1745, and died in 1812. His third son, Nathan Meyer, who was the founder of the London branch, was sent to Manchester in 1797, settled in London in 1805, and died in 1836 while on a visit to Frankfurt. Through one of his agents, a man named Roworth, he was informed of the victory of Waterloo before anyone else in London; but the story that he himself brought the news from Waterloo and was able to open large financial transactions before it was generally known, is declared to be mythical. The Evelina Hospital for Sick Children in Southwark was named after one of his grand-daughters who died in 1866. Passing over George Romney, painter (1734–1802), William Roscoe, historian (1753–1831), and Lord John Russell, statesman (1792–1878), we come to Dante Gabriel Rossetti, painter and poet, who was born in London in 1828; his father, Gabriele Rossetti, a native of Vasto in the kingdom of Naples, came to England in 1824 and was appointed professor of Italian in King's College in 1831. Rossetti's poetic faculty was developed early. The ballad of "Sir Hugh the Heron" was written in 1840 and printed two years later; "The Blessed Damozel," "Retro me Sathanas," and other remarkable pieces were written about 1847. His collected "Poems" were published in 1870, and "Ballads and Sonnets" in 1881. From about 1870 to the end of 1881 he was addicted to the use of chloral, which ruined his health, and he died at Birchington, near Margate, in 1882. The present life of him is from the pen of Dr. Richard Garnett, who says: "Rossetti is a unique instance of an Englishman who has obtained equal celebrity as a poet and as a painter. It has been disputed in which class he stands higher; but as his mastery of the poetic art was consummate, while he failed to perfectly acquire even the grammar of painting, there should seem no reasonable doubt that his higher rank is as a poet."

The biographies of medical men are thirty-one in number. George Rogers was born in London in 1618, graduated as M.B. at Oxford University in 1642, was incorporated as M.D. in 1648, was elected a Fellow of the College of Physicians of London in 1664, was Harveian orator in 1681, treasurer in 1683–85, and president in 1688. He died in 1697. Peter Mark Roget was born in London in 1779, his father being a clergyman of Geneva. He graduated as M.D. at Edinburgh University in 1798 and travelled on the continent for some time, after which he was in 1805 appointed physician to the Manchester Infirmary and became one of the founders of the Manchester Medical School. In 1808 he removed to London where "he pursued a career of almost unexampled activity for nearly half a century." He lectured at the medical schools in Great Windmill-street and Aldersgate-street, was the first holder of the Fullerian professorship of physiology at the Royal Institution, was a founder of the Society for the Diffusion of Useful Knowledge, and wrote for its "Library of Useful Knowledge" treatises on electricity, galvanism, magnetism, and electro-magnetism. He was elected a Fellow of the Royal Society in 1815 and was secretary from 1827 to 1849. In 1831 he was elected Fellow of the Royal College of Physicians of London and delivered the Goulstonian Lecture in the following years. In 1837 and the subsequent years he took an active part in the establishment of the University of London, and was a member of the Senate until his death, which occurred in 1869. George Rolleston was born near Rotherham in 1829. He graduated at Oxford University as B.A. in 1850, M.B. in 1854, and M.D. in 1857. After becoming qualified he held a hospital appointment in Smyrna, and in 1857 was elected physician to the Radcliffe Infirmary in Oxford. In 1860 he was appointed the first Linacre professor of anatomy and physiology at Oxford and filled the chair with conspicuous ability until his death in 1881. In 1873 he delivered the Harveian Oration of the Royal College of Physicians of London. Tancred Robinson, born in Yorkshire between 1655 and 1660, graduated at Cambridge University as M.B. in 1679 and as M.D. in 1685. He was appointed Physician in Ordinary to George I., by whom he was knighted. He published numerous observations in connexion with natural history and botany, and died at an advanced age in 1748. Joseph Rogers, born in 1821, commenced medical practice in London in 1844, and in 1856 was appointed medical officer to the Strand Workhouse. "In 1868 his zeal for reform brought him into conflict with the guardians, and the President of the Poor-law Board, after an enquiry, removed him from office. In 1872 he became medical officer of the Westminster Infirmary. Here also the guardians resented his efforts at reform and suspended him; but he was reinstated by the President of the Poor-law Board, and his admirers presented him with a testimonial consisting of three pieces of plate and a cheque for £150. He was the founder, and for some time president, of the Poor-law Medical Officers' Association." He died in 1889. George Leith Roupell was born in Sussex in 1797. He studied medicine at Cambridge University, graduated M.B. in 1820, M.D. in 1825, and in 1826 was elected a Fellow of the Royal College of Physicians of London. He was censor for three years and Croonian lecturer in 1832 and 1833. In 1837 he read before the College "Some Account of a Fever prevalent in the Year 1831," for which he proposed the name "febris typhodes rubeoloida," and which seems to have been epidemic cerebro-spinal meningitis. He died from cholera in London in 1854. James Russell, born in Edinburgh in 1754, was admitted a Fellow of the Royal College of Surgeons of Edinburgh in 1777, and was president of the College in 1796–97. From 1786 onwards he gave clinical lectures in surgery until in 1803 he was appointed to "the clinical and pathological professorship of surgery," a chair founded by the town council of Edinburgh entirely in consequence of his exertions, and which he transferred to James Syme with the sanction of the Lord Advocate in 1834. He died in 1836. James Ross, born at Kingussie, Inverness-shire, in 1837, graduated at Aberdeen University as M.D. in 1864, and in 1876 was appointed pathologist to the Manchester Infirmary. In 1881 he published "A Treatise on the Diseases of the Nervous System," in two volumes, which was the first large modern text-book in English on its subject and was widely read. He was elected professor of medicine in Owens College, Manchester, in 1887, and died in 1892. Samuel Rowe, born in Cheshire in 1835, received his qualifications to practise medicine in 1856, obtained an appointment on the army medical staff in 1862, and was sent to Lagos, where he filled various offices, both administrative and medical. In 1865, while home on leave, he graduated in medicine and surgery at Aberdeen University. In 1866 he returned to West Africa and had a large share in withstanding the earlier attack of the Ashantis in 1873. In 1877 he was appointed Governor of the West Africa Settlements, and was knighted as K.C.M.G. in 1880. He died at Madeira in 1888. William Roxburgh, born in Ayrshire in 1751, graduated as M.D. at Edinburgh University and obtained an appointment in the East India Company's Madras establishment in 1776. An accomplished botanist and cultivator of useful plants, he sent hundreds of drawings to England, and in 1793 was appointed

Digitized by Google

superintendent of the Calcutta Botanic Garden. He returned to England in 1805 and died in Edinburgh in 1815 His "Hortus Bengalensis" was published in 1814, and his "Flora Indica" in 1820, 1832, and 1874. B yan Robinson, born in 1680, graduated M.D. in 1711 at Trinity College, Dublin. He was anatomical lecturer there in 1716–17, and in 1745 was appointed professor of physic. In 1712 he was elected Fellow of the King and Queen's College of Physicians in Ireland, and was president in 1718, 1727, and 1739. He had a reputation both as a medical and a mathematical writer. He died in 1754. John Forbes Royle was born in Cawnpore in 1799 and was educated in Edinburgh. In 1819 he was placed on the medical staff of the Bengal Army and in 1823 was chosen superintendent of the garden at Saharunpore. In 1831 he returned to England and in 1837 was appointed professor of materia medica in King's College, London. He was the author of numerous valuable works on Indian plants, and also published a Manual of Materia Medica. He died in 1858.

Although George John Romanes was not a medical man, it seems right to include his biography among the present excerpts on account of his eminence as a biologist. He was born in Canada in 1848 and was brought to England at an early age. From 1874 to 1876 he studied under Professor Burdon Sanderson in the physiological laboratory at University College. Researches by him on the influence of injury on the excitability of motor nerves and investigations on the nervous and locomotor systems of the medusæ and the echinodermata were subsequently communicated to the Royal Society, and he was elected a Fellow of the Society in 1879. He died at Oxford in 1894. In addition to the papers already mentioned his works included treatises on mental evolution, organic evolution, and Darwinism, some of them not being published till after his death.

LIBRARY TABLE.

Elements of Human Physiology. By ERNEST H. STARLING, M.D. Lond., Joint Lecturer on Physiology at Guy's Hospital. Third edition. London: J. & A. Churchill. 1897. Price 7*s.* 6*d.*—We have already had occasion to notice with praise this manual, written by a physiologist who has been for some time past engaged in teaching physiology in a large medical school in the metropolis and who is therefore well qualified to judge of the requirements of the medical student and of the amount and kind of physiological knowledge that will prove most serviceable in practice. The present edition differs but little from its predecessors and is not overburdened with details in regard to the construction of scientific instruments, a knowledge of which is of little value to the student. The more important facts in the sections devoted to each of the functions of the body are given clearly and well and the work as a whole is well up to date. As an evidence of this we may refer to the chapter devoted to the subject of the coagulation of the blood, in which the recent views of Hammarsten are given. The danger of all manuals is that of increase of size by the interpolation of new matter. It is satisfactory to find that Dr. Starling has resisted this temptation and that the present only exceeds the preceding edition by about a dozen pages. The work may be regarded as one of the best of those which seek to compress the wide subject of physiology into a reasonable compass. Fourteen fresh woodcuts have been introduced.

Diseases of the Eye, a Practical Handbook for the use of General Practitioners and Students. By CECIL EDWARD SHAW, M.D., M.Ch. R.U.I., Ophthalmic Surgeon to the Ulster Hospital for Children and Women, Belfast. With Illustrations and a Test Card for Colour Blindness. London: J. & A. Churchill. Pp. 103.—This short treatise is intended by the author to furnish the general practitioner and the student with a concise account of the principal forms of ophthalmic disease which they are likely to meet with in practice. The descriptions of disease are sufficiently clear and accurate, and the author has, we think, done wisely in not burdening his book with the details of ophthalmoscopy which can only be learned in the out-patient room or in the wards of a hospital or with an account of operations which are only undertaken by those who are devoting themselves to ophthalmic practice and have at hand the appropriate instruments in good order. An exception is made in regard to the operation for the extraction of cataract, and an observation is added to the account given to the effect that many surgeons now omit the iridectomy when removing cataract, the advantage being that it simplifies the operation and gives a better pupil; but in England the consensus of opinion is still in favour of doing iridectomy as the safer method. The modes of determining errors of refraction are given in some detail and are intelligible to any student.

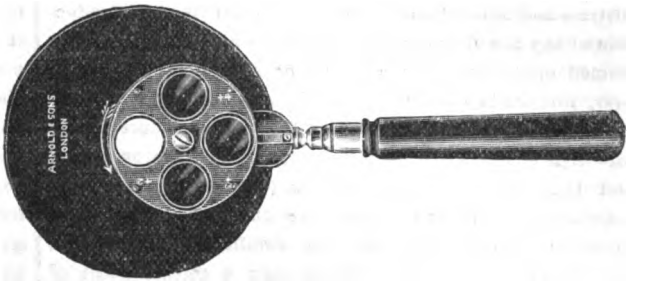
The Mathematical Psychology of Gratry and Boole Translated from the Language of the Higher Calculus into that of Elementary Geometry. By MARY EVEREST BOOLE. London: Swan Sonnenschein and Co., Limited. New York: G. P. Putnam's Sons. 1897. Pp. 116. Price 3*s.*—Lovers of abstract speculation will find much to interest them in this little book, which is a kind of primer or introduction to the generalisations contained in the "Laws of Thought" published in 1854 by the late Mr. Boole, Professor of Mathematics in Queen's College, Cork, as well as to those contained in the earlier work "Logique," written by M. Gratry. Its merits, however, are somewhat impaired by the circumstance that the gifted authoress has presented the elements of the mathematical part in a manner so very concise that a psychologist unacquainted with mathematics might be pardoned if he fell into the error of supposing that the differential calculus is as hazy and indeterminate as some portions of his special subject. The dedication to Dr. Maudsley shows that the infinitesimal calculus is the process chiefly in question, but Mrs. Boole's explanation of it is mainly a diagram of a differential parallelogram together with the tangent to a curve. Not many pages would, however, have been required both for showing the process of differentiation of a few selected expressions, and also for giving some simple examples of the results obtained by its aid in particular instances, such as in the drawing of tangents to parabolas of the second or third order, or in finding the maximum rectangle that can be inscribed in an equilateral triangle. Psychologically, the resultants (i.e., the diagonals) of parallelograms of forces are to be interpreted as the necessary compromises of conflicting views and interests in the ordinary affairs of life (p. 34), and the circumstance that the evanescent differentials of a mathematical function have a definite ratio to one another is to be understood as follows (p. 46): "For those who are seeking from the calculus information about human psychology it is a fact of overwhelming importance that the special knowledge about the curve which is to be got by means of the varying ratio between two fictitious elements comes only at the moment when these elements vanish; i.e. when the subject matter which has been under investigation vanishes to No-Thing." The most practical part of the book is perhaps Chapter VII., which treats of the method of drawing inferences from antagonistic arguments. The facetious puerilities introduced into the description of a fluxion should be omitted in a future edition.

The Law of District and Parish Councils. By JOHN LITHIBY, LL.B. London: Effingham Wilson and Sweet and Maxwell. Second edition. Price 15*s.*—We drew attention to this book and expressed a warm appreciation of Mr. Lithiby's work when the first edition

Digitized by Google

appeared. That is now three years ago, and the interval affords full justification for a second edition of the work. The changes in the law are not, however, very momentous, and it can hardly be matter of surprise that the editor of these statutes has taken somewhat easily the task of preparing a second edition. The result, however, is a little disappointing, for although the new matter is to be found by those who search for it within the book it is not always to be found where it should be. To take an illustration of what we mean. On page 69 the qualifications of parish councillors are set out from the Act of 1894 and comprise *inter alia* a twelve months' residence. On page 396 the amending Act of 1897 is set out, and shows that this particular qualification has been abolished in the case of candidates who enter into residence before March 25th in any year. The amendment has not, however, been incorporated in the notes to the earlier statute and Mr. Lithiby's text in one place is therefore misleading. The book is a great repertory of information, but the impression which it leaves upon our mind is that it would be greatly improved by careful re-editing.

Liza of Lambeth. By W. SOMERSET MAUGHAM. London: T. Fisher Unwin. Price 3*s.* 6*d.* — The author of this powerful if somewhat sombre work is, the publisher informs us, a medical man. He certainly has one valuable quality for one in his profession—namely, the gift of observation — and another equally valuable, though not so common, literary skill. The story inevitably invites comparison with Mr. Morison's "Child of the Jago," which deals with a similar class of society, and though not so much of a "story" is to our minds superior in that it avoids the somewhat Dickens-like pathos which is the blemish of Mr. Morison's otherwise excellent book. Mr. Maugham's picture of life among the poor is not a pleasant one, though wonderfully graphic, neither do we mean to contend that all the poor are like his characters. But that there are such among the lower classes no one who has ever done any work among them will deny for a moment. The way in which the women talk about their children, the number of "misses" they have had, the ghoul-like pleasure they take in funerals and deaths, are all admirably described, and the scene at Liza's death-bed, where her mother discourses to a select circle of friends upon the difficulty she and her neighbours had in getting her husband into his coffin, is true to the life. The animal-like wooing of Jim and the death of Liza are the two most powerful scenes in the book, but should Mr. Maugham write another book—and we hope he will—he might choose a somewhat less sordid subject.



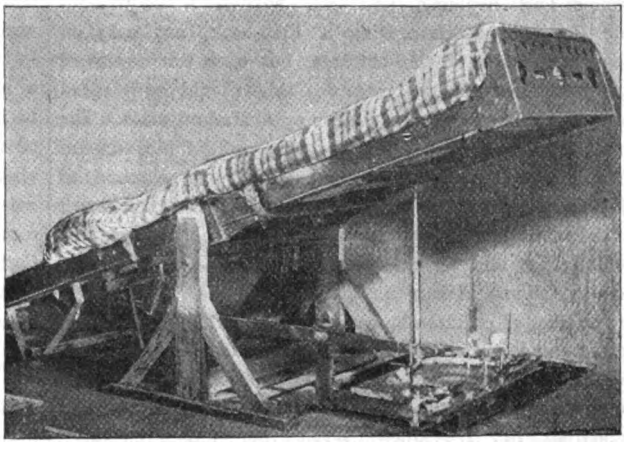
JOURNALS AND REVIEWS.

IN the October number of the *Phonographic Record* Dr. Griffiths narrates a case of rheumatism followed by pericarditis and double pneumonia in which oxygen inhalations are said to have averted death, and Mr. Norman Porritt discusses the action of the coal tar derivatives. He regards the effect of this class of bodies upon the hæmoglobin as the explanation of their toxic action. We learn from this number that Sir William Gowers has been elected Patron of the National Federation of Shorthand Writers' Associations in place of the late Sir Isaac Pitman, and that the Society of Medical Phonographers intends to entertain him at dinner to congratulate him upon the honour which Her Majesty the Queen has recently conferred upon him.

New Inventions.

NEW AURAL AND THROAT MIRROR.

WITH this mirror an enlarged, well illuminated, and distinct view of the tympanum may be obtained. It is a concave mirror three inches in diameter with a sight hole of 15 mm. and having a focal distance of about seven inches. A rotary disc at the back carries three lenses, + 2 D, + 3 D, + 4 D, which in turn can be moved opposite the central



hole. The best results may be had by holding the mirror about midway between the eye and the object. If the observer be presbyopic he can use the mirror in the usual manner, selecting the lens which suits him. Messrs. Arnold and Sons, West Smithfield, E.C., are the makers.

THOS A. GOODCHILD, L.R.C.P., L.R.C.S. Irel.
Queen's-road, N.E.

A MOVING BED.

AN ingenious method of communicating a gentle rhythmic movement to a bed has been invented by Mr. Walker, Hartwood, West Calder, N.B. It is so designed as to be easily adapted for use either in public hospitals or in private houses. The bed is fixed at its centre, and by means of hydraulic machinery of simple construction and noiseless action the head is alternately raised and lowered, so as to give the bed a gentle movement upwards and downwards. The accompanying illustration gives a good idea of the whole arrangement. The bed was for some time in operation in the Edinburgh Royal Infirmary, where, through the kindness

of Sir Thomas Grainger Stewart, many members of the medical profession have been enabled to witness its effects. In many neurotic affections it has been found to produce beneficial results, more particularly in cases of insomnia and restlessness. It has, moreover, been of use in digestive, circulatory, and respiratory troubles.

THE LANCET.

LONDON: SATURDAY, OCTOBER 16, 1897.

IT is probable that only a few of those who are practising medicine, and scarcely any of the laity, are aware of the distress and annoyance that are occasioned by the introduction of any one of the group of diseases which are collectively termed ophthalmia into a school or asylum. Those, however, who are in charge of such institutions know only too well that to effect a cure in the patients unremitting attention is required, extending over many days or weeks, and that the most persistent and carefully considered measures often fail to prevent the disease from spreading to those who occupy the same dwelling-rooms or who use the same lavatories. When once a certain form of the disease has gained a firm footing in a colony of children years often elapse before it can be regarded as eradicated, whilst impairment of vision of a more or less serious nature is a very common result in those who have been affected. Such cases, it has been justly remarked, whilst they interfere with discipline and interrupt education, seriously handicap the victims in their struggle for existence. Their wage-earning value is reduced. The chances of a relapse into pauperism are multiplied, and there is always a risk that the disease may be communicated to those with whom they are brought into contact. Owing probably to the frequency with which their attention is directed to ophthalmic disease and the expenses which an outbreak entails, the Local Government Board recently directed an experienced and able ophthalmic surgeon, Mr. SYDNEY STEPHENSON, to investigate the ophthalmic state of Poor-law children, with the result that that gentleman has inspected a large number of schools and asylums, and has written a very valuable Report, just issued as a Blue-book, not only on the present state of the children, but upon the causes of the prevalence and the measures that should be adopted to diminish or altogether abolish ophthalmic disease. The report is worthy of perusal by every ophthalmic surgeon as well as by the matrons and other officers attached to large schools; and great praise is due to Mr. STEPHENSON for the very painstaking manner in which he has conducted his inquiries and for the sound, practical, common-sense remarks and suggestions that are to be found on every page. The number of children he has examined is 17,002, of whom 860 were under two years of age. The ophthalmic affections which commonly present themselves in schools and asylums are acute and chronic ophthalmia with their effects, and blepharitis, the last-named disease, though chronic, being comparatively unimportant. The acute ophthalmias are divisible into muco-purulent and purulent. It is gratifying to find that acute purulent ophthalmia is practically absent, although 860 were, as just stated, only infants. Muco-purulent ophthalmia or blight, on the other hand, is not uncommon, existing in 4·72 per cent. of the total number of children examined. This affection occasionally appears in the form of an epidemic, associated probably with certain atmospheric conditions, but does not last long, and even when not subjected to treatment does not produce any serious or permanent lesion of the eye. The chronic and by far the most important forms of disease which are prevalent in schools are follicular ophthalmia and trachoma. Mr. STEPHENSON has arrived at very positive conclusions in regard to the follicular disease, and his large experience gives great weight to his opinion. The disputed question on which so many essays have been written both at home and on the continent as to the identity of purulent, follicular, and military or Egyptian ophthalmia with trachoma, it is now pretty clear, is to be decided in the negative. Purulent ophthalmia has its own micrococcus and does not constitute a stage, as some have thought, of trachoma. Follicular disease has also in all probability its own specific virus. It is exceedingly common among children and is usually regarded as associated with overcrowding and vitiated and damp air. Mr. STEPHENSON, however, is not satisfied on this point and does not consider sufficient evidence is forthcoming to demonstrate that it is the outcome of an unhealthy environment. It was present in 2·24 per cent. of 10,967 children examined in the district and separate schools. Trachoma—the "granular lids" of many English writers—is the real scourge. It is a separate affection and also probably has a microbe of its own. The supposed transition of follicular disease into trachoma has arisen, it is thought, from children with follicular disease being placed in wards with trachomatous children, from whom they have contracted that infectious disease. Trachoma, then, remains as the most important of all the forms of ophthalmia affecting schools and asylums. Insidious in its origin and progress, revealing itself in its early stages only to careful examination, it is very persistent, leads in most instances to haziness of the cornea, and not infrequently to loss of useful vision; it has the obnoxious quality of being highly infectious. Amongst the 17,002 children examined no less than 973 cases of trachoma were found, very few instances, however, occurring in the children under two years of age. Lesions of a more or less serious nature of the cornea were found in 277 cases, the ill-effects ranging from slight impairment of vision to almost complete blindness. The institutions visited by Mr. STEPHENSON were separate schools or those belonging to a particular parish, district schools which receive children from more than one union or parish, Roman Catholic certified schools, the training ship *Exmouth*, the Ophthalmic School at Hanwell, the certified convalescent homes, and, lastly, the metropolitan infirmaries and workhouses. It is noticeable that not a single separate school was free from trachoma, the number of cases varying from 1·63 to 13·15 per cent. of the inmates, the average being 4·60 per cent. In the district schools 3·65 per cent. were suffering from active trachoma and 1·37 per cent. bore traces of having formerly suffered from it. In the workhouses the proportion was 6·41 per cent.; in the infirmaries, 5·60 per cent.; in the Roman Catholic certified schools, 7·48 per cent.; and in the *Exmouth*, 0·84 per cent. Long experience and the visitations of many institutions

Digitized by Google

have enabled Mr. STEPHENSON to discover weak points in their construction and management that might easily pass unnoticed, but which have an important influence on the propagation of ophthalmic disease. Details are given in the report in regard to the warming, ventilation, and the supply of light to the school and other rooms, to the disposition of the closets and lavatories in regard to other apartments and their drainage, the size and cleanliness of the baths, the supply of towels, the storage of clothes, and many other particulars, all of which are now carefully inquired into by an excellent board of inspectors.

The most valuable portion of the report is that containing suggestions with regard to the stamping out of trachoma. The two principles on which Mr. STEPHENSON proceeds are exclusion and eradication. In regard to the first, he considers that before any children are admitted, however healthy they may appear to be, they should be subjected to careful and skilled medical inspection and they should undergo a period of probation in some school specially set aside for the purpose. Such a proceeding would materially contribute to the abolition of trachoma by preventing its admission and the possibility of its being grafted on follicular ophthalmia. Where trachoma has unfortunately gained a footing its eradication must be attempted by isolating the affected children and placing them under the best conditions for recovery in a central school where they may be properly classified and specially treated whilst they continue their education. Periodical inspections of all the schools should be made by experts so that the affected may be weeded out without loss of time. Indirect means for the suppression of disease should not be omitted, such as attention to washing and bathing when contagion most easily occurs, and the improvement of all conditions of environment, any defects in which tend to weaken the individual and lower his power of resistance, such as defects in ventilation, floor and cubic space, warming, food, exercise, clothing, and drainage. Attention to these particulars, it may reasonably be anticipated, will greatly diminish, if it does not completely exterminate, this scourge of large schools, and we may hope that in a few years, as the public mind becomes more enlightened on the subject, the severe strictures which Mr. STEPHENSON has found himself compelled to make on the hygienic conditions that surround the Poor-law children will no longer be applicable and that chronic ophthalmia will be a thing of the past.

The case of the *Exmouth* training ship which succeeded the *Goliath* demonstrates the utility of preventive measures. A correspondent in describing in our columns in 1874 the condition of the *Goliath* pointed out the danger of the mode in which the washing of the boys was conducted, and shortly afterwards Mr. NETTLESHIP found more than one-third of the boys suffering from granular lids. By adopting wise preventive measures the proportion of cases of trachoma has now fallen to less than 1 per cent. The conclusion is obvious.

BIRMINGHAM, with its half a million of people, its large medical charities, and its citizens of municipal and even Imperial fame, well deserves the attention which has been given to it by our Special Commissioner, whose four papers on Hospital Abuse as illustrated in that city will interest all students of that subject. Thirty years ago some of the first suggestions in favour of an improvement in club practice and the remuneration for it came from a Birmingham practitioner, Mr. HESLOP. The provision for medical relief under the Poor-law in Birmingham is of the stateliest kind. Its hospitals and dispensaries are so attractive that not less than one-third of its inhabitants in the year become hospital patients. The late Mr. SAMPSON GAMGEE brought the organisation of the Hospital Saturday Fund to such perfection that the contributions of the workmen exceed those of the wealthy. For every £100 subscribed more than £200 are received in registration fees. Such substantial contributions entitle the workmen to a powerful voice in the management of the charities, and our Special Commissioner makes the startling statement that there is hardly a hospital in the town which would not be bankrupt if the workmen withdrew their support. The working classes are naturally proud of their contributions, and the governors of the different institutions are only too willing to meet their natural pride by every concession that they can make to their views. One significant little fact is recorded by our Commissioner. One of the medical institutions which is said to be most abused in Birmingham is the General Dispensary. The Hospital Saturday Fund makes a large contribution to this dispensary—something like £600 a year. By way of return for this sum and other sums accruing from the purchase of tickets—for extra tickets may be bought for 4*s.* at the time of illness—the committee of the Birmingham General Dispensary some years ago resolved to omit from the letters supplied to workmen's societies, &c., the words "object of charity," leaving it to be understood that the medical service rendered was really paid for as it might be in a provident dispensary and that the person receiving it was under no charitable obligation to the institution or its medical officers. Naturally, a large proportion of the patients treated at this dispensary are comfortable people, well able to pay reasonable remuneration to a medical man. It was ascertained that 25 per cent. of the patients at one of the branches were in receipt of £100 a year. Needless to say that the same abuse has been shown by our Commissioner to obtain in the general hospitals and in the Eye Hospital and institutions that receive large contributions from the Hospital Saturday Fund and further sums in the shape of registration fees. The working of the system is shown in many cases. Men with large incomes saved by thrift and industry see their less provident friends get all they want at the hospitals and wonder why they should be expected to pay the ordinary fees—and so they get their cataracts extracted and other operations performed for nothing too.

It must not be supposed that this great change in the conception of hospitals and dispensaries is still quite complete. There are still men who realise that the contributions of the workmen to the charities by which they are so much benefited are essentially free gifts for the good of others rather than themselves. They were asked for originally by Mr. SAMPSON GAMGEE, as they are asked for now by Hospital Saturday and Sunday funds, as helps to enable the managers of hospitals to meet urgent cases of sickness and accident. Alderman COOKE, chairman of the Hospital

Digitized by Google

Saturday Fund, said emphatically to our Commissioner: "A subscription to a fund, whether it be weekly or yearly, gives no right whatever. If a man or woman presents himself or herself at a hospital and demands treatment as a right bought by a subscription to the Hospital Saturday Fund he or she takes an absolutely unjustifiable position. The subscription carries with it no right; the princely gift of so many thousands per annum carries with it no equivalent. It is a free gift to the free work of the medical charities of the town."

We cannot too strongly endorse and enforce the view laid down so clearly by Alderman COOKE. If it is not shared by the workmen of Birmingham who give so generously to the charities we are persuaded that it is due to a misunderstanding of the very nature and origin of the institutions which they support. Let us illustrate our argument by a London case. It is well known that a London employer of labour has lately placed £120,000 or more at the service of a London hospital and all men recognise the generosity of the gift. But what would be the change in the public view of it if this gentleman had accompanied it with the conditions that he and his family, his workmen, his servants, and his employés generally had to be treated in all their ailments in consideration of his gift? The gift would be robbed of all its grace and its virtue and the giver would be little thanked. It is not otherwise with the systematic and generous contributions of the workmen of Birmingham to her charities. They are very fine so long as they are given for the use of the institutions as originally defined, but they bear a very different aspect if they are used to turn these institutions into cheap dispensaries for ordinary cases. Yet it is said that Mr. SMEDLEY, a man of wealth and strong humanitarian feelings, who is, we presume, in succession to Mr. SAMPSON GAMGEE, the great promoter of Hospital Saturday, regards the Hospital Saturday Fund as favouring the idea that the hospitals are provident clubs. He admits the great abuse of the out-patient department, but, contrary to the opinion of the great majority of medical men, he does not recognise any serious abuse of hospitals in the sense of their being frequented by numerous patients who can afford to pay private practitioners. The great point is to determine whether hospitals and dispensaries are for those who are in work and for their ordinary ailments or only for the poor and for those in exceptional circumstances of disease or accident? To judge from the tenour of our Commissioner's reports the Hospital Saturday Fund is being used so as to convert the medical attendance on those who contribute to it into a huge charity, much as that word is disliked. It is not even a provident arrangement, for that would attempt to pay the medical men concerned more or less adequately. It is a huge and somewhat shabby device to get medical attendance without paying for it in the same honest sense in which a British working man pays for his bread and his beer.

We wish we could see in our Commissioner's account proof of any serious realisation of the plight in which the profession is left by such a misuse of hospitals or of any adequate effort to grapple with the situation. Birmingham has great notions of the power of municipalisation; but is the medical profession to be municipalised out of its position and its function? Are the duties of half a million people to the medical profession to be discharged by charitable contributions and petty registration fees to hospitals? Is the profession on this subject to be divided into two hostile parties—one seeing itself magnified by the hospital system and the other seeing itself degraded or extinguished? Our brethren in Birmingham have a great opportunity of solving some great questions; but unless more unity and decision are shown than have yet appeared the profession will be given away by those who ought to lead and uphold it.

THE most important subjects dealt with under the section of public health and local administration in the annual report of the Local Government Board are the working of the Sale of Food and Drugs Act, and the efficiency of the metropolitan water-supply. The urgency of all the questions implied under the consideration of these branches of public administration increases, and the material before us in the twenty-sixth report which has just been issued has increased in proportion, so that we shall make no attempt to deal now with the immense Blue-book as a whole, but shall limit our remarks at present to a review of the working of the Sale of Food and Drugs Act.

With reference to the working of this Act the twenty-sixth report is of special interest because in the statistics therein recorded a series of twenty years is completed, and therefore an approximate measure may be made of the real work that the Act is effecting in connexion with the suppression of food adulteration. To us the interest in this fact is intensified when we reflect that the Sale of Food and Drugs Act had its origin in the fearless exposure of gross adulteration and fraud which the Founder of THE LANCET brought to light at a time when legislation exercised absolutely no control in this matter. Adulteration in the days of THE LANCET Analytical Sanitary Commission was not only a species of fraud upon the public, but, as was shown, a positive danger to the public health. Slow as is the reduction year by year of the total number of adulterated samples, yet the fact remains that this number has steadily declined during the last twenty years, so that while in the year 1877, when the results of the analysis were for the first time tabulated, 19·2 per cent. were condemned the proportion has fallen to a little over 9 per cent in the official year just closed. As to the injurious forms of adulteration in vogue thirty or forty years ago, they have "almost, if not entirely, disappeared." While it is, on the whole, true to say that the public are now cheated rather than poisoned, yet there should be no reason why the extent of this cheating should not be further reduced. This can be done even under the provisions of the present Act, but more vigilance on the part of the authorities entrusted with the working of the Acts will have to be exercised. Abundant evidence on this point is afforded by the fact that where more active measures have been taken, especially in increasing the number of samples submitted for analysis, the proportion of those reported against has gradually declined. This is well illustrated in the case of the district of St. Mary Newington, where no action whatever had been taken under the Acts up to the end of 1887. In the following six years samples were taken at the rate of thirty-three per annum, and over a third of

Digitized by Google

them proved to be adulterated. In 1894 the percentage of adulterated samples amounted to 30. In the following years the authorities instructed their officers to take over 1000 samples, and legal proceedings were instituted where an offence had been committed, with the result that in 1896 the proportion of condemned samples was brought down to 11 per cent. We have often reflected upon the neglect of the authorities to avail themselves of the powers they possess, and our views in this regard are now fully justified in the instances just quoted. Again, nothing could be more absurd than the extraordinary leniency shown by magistrates towards offenders in regard to fines. Especially is this so in the case of milk and spirits. The fines in some cases were so trifling that it was clear to the blindest that it would pay an offender to adulterate his wares again and again during the year and undergo the resulting legal punishment, so big was the price which he got for the added water and so trifling were the fines exacted from him. We would have these shabby rogues dealt with in the salutary way suggested in the recommendations of the new Bill—that is to say, we would have published as widely as possible *and at the expense of the offender* the fact of his committal for fraudulent practice, and in some instances, so serious do we hold the offence of adulteration, justice would not be overdone if the premises of the offending person were placarded with a full advertisement making a similar announcement.

London still leads the way in regard to the extent of milk adulteration, the proportion of watered samples being 17·7 per cent., as against 9·1 for the rest of the country. The Local Government Board regard this as a matter for regret, and so do we. And why is it so? For the simple reason that a standard of unimpoverished milk has not yet been fixed by statute. The fact that milk of the poorest possible quality is regarded as genuine gives the unscrupulous milkman the easy device of watering milk of good rich quality down to zero. The London milkmen are ever on the watch to catch the authorities sleeping since it has been found that on taking samples of milk on Sunday no less than 47½ per cent. in one instance were found to be adulterated. But "as soon as the local authorities seriously take the matter in hand the Sunday rate of milk adulteration is reduced." Here is another practical lesson that increased vigilance on the part of the authorities is largely, though not entirely, what is required. The Act even in its present form would have presented but a few objections had not the local authorities in so many instances failed to perform their duty. As it is, the extent of adulteration has been reduced to 9 2 per cent., which is the lowest figure yet attained.

The working, therefore, of the Sale of Food and Drugs Act has not been without satisfactory results, and we confidently anticipate that with the new modifications of the present Act, which a new Bill will embody, the public will have a still stronger guarantee of being supplied not only with unadulterated food but with food of a desirable standard of purity and quality. It is curious that the highest percentage of adulteration recorded during the past year has been for spirits, which is the only article for which a standard of strength has been legally fixed. In many instances the proportion of water was so large as to make the selling of the mixture exceedingly profitable. Some people have tried to justify the publican in selling diluted spirits on the plea that he is selling a much less intoxicating mixture than the Act would compel him to sell. Such an argument is utterly beside the point at issue. Whisky (for instance) is one price, and water quite another, and when the purchaser pays for the former the vendor has no right to give him the latter. There are other points in the report with which we have not space to deal, but in the main they relate to those defects in the present Act which we hope will be removed in the new Bill, the recommendations in which were drawn up in a report by the Select Committee on Food Products Adulteration in July last. The Local Government Board report observes that "many importants amendments to the law are recommended, and we have under consideration the question of promoting legislation on the subject." The pressure of public business however was the excuse of the leader of the House of Commons for not dealing with the Bill last session, but we trust that it will be considered at an early stage when Parliament reassembles.

MR. VICTOR HORSLEY has been elected a Direct Representative for England and Wales by a substantial majority over his only serious opponent, Sir WALTER FOSTER. The profession must wait until the day fixed for the declaration of the poll for all the exact figures in a contest which, in the personalities of the candidates and in its importance for the future of direct representation, has been one of real interest and importance to the whole profession. It would be premature to enlarge upon these details at the present moment, but we need not defer the expression of our great satisfaction at Mr. HORSLEY'S election, inasmuch as we have favoured his cause from the beginning of the contest into which the profession was so unexpectedly thrown by the resignation of Dr. R. R. RENTOUL. The event will immediately restore some of the lost prestige of direct representation. Mr. HORSLEY'S ardour of temperament and strong opinions in regard to the defects of the Medical Acts and to the imperfect use of them by the General Medical Council are well known, and these perhaps will lead some to fear that in the discussions which he will invite his zeal may outrun his discretion. We do not think so. Not only the responsibilities of office but also the very sincerity with which he wishes to procure reasonable reforms will moderate the pace with which Mr. HORSLEY will seek to urge the Council to adopt his ideas. The General Medical Council is a body capable of great resistance. It will be strengthened by the presence of a member with strong convictions of the necessity for more actively asserting its functions, and we do not believe that it will blindly refuse to listen to reasonable arguments in support of such a view, or, if necessary, in support of a demand for larger powers than it at present possesses. But the Council cannot be "rushed." If a reform programme is to find supporters in the Council it must be presented by men who are perfectly clear and convinced in their own minds, and can preserve their own consistency. The strength of Mr. HORSLEY'S position is that while standing as a surgeon high in the world of science, and

Digitized by Google

having only the smallest personal interest in any action of the Council or in any alteration of the Medical Acts, he has shown for years the greatest possible interest in all matters which affect the rank and file of the profession. He is, besides, in virtue of his position familiar with the latest aspects of medical education, and so will be in a position to take a useful part in promoting those improvements in teaching and in examinations which the reports of the Council's inspectors show to be so much needed. On all these grounds we rejoice to record the success of Mr. HORSLEY in this important by-election. His conduct during the contest has been perfect in temper and in argument. He paid the electors the compliment of avoiding all claptrap, all humiliating alliances and concessions, and of discussing the most delicate subjects with gravity and moderation. We also congratulate the profession on their choice. Their Direct Representatives, if they are to be of any use, must be men of high character and standing; and they have chosen such a man. Sir WALTER FOSTER will not, we trust, be much discouraged by losing the battle, for certain of his supporters may take most of the blame. He found Mr. HORSLEY in the field and well advanced in the contest. It would have been more gracious to have recognised Mr. HORSLEY'S claims and to have given the profession the advantage and the pleasure of an uncontested election; but he decided otherwise, and has the satisfaction of having been beaten by no mean opponent.

Annotations.

"Ne quid nimis."

"VACCINATION" AGAINST TYPHOID FEVER.

AT a time when public attention is so strongly drawn to typhoid fever by the epidemic at Maidstone and the sensational notices on the "posters" of the evening papers it may be well to remind medical men of certain points in regard to the means by which the contagion is spread and the prophylactic measures which may be adopted. A contaminated water-supply has been so much discussed in relation to the Maidstone epidemic that we need not enter further into that part of the subject; a thorough treatment of the stools by means of disinfectants such as carbolic acid and perchloride of mercury is also adopted as an ordinary routine measure; similar precautions as regards the urine, however, are not usually taken, but as the pathogenic bacilli have been found in the urine of patients suffering from typhoid fever the suitable disposal of all the patient's excreta should be carefully superintended. Numerous papers have been published from time to time demonstrating the spread of the infection by milk, vegetables (notably watercress), oysters, &c., and we need not comment further on similar possible channels of infection. We have received a letter from Dr. A. E. Wright, Professor of Pathology at the Army Medical School, Netley, reminding us of a paper published by himself and Surgeon-Major D. Semple, Assistant Professor of Pathology at the same school.[1] In this communication the writers detailed the results of experiments which they had made with anti-typhoid "vaccines." Most of the "vaccinations" were performed upon medical officers of the Army or Indian Medical Services, or upon surgeons on probation who were preparing to enter those services, so that the results were carefully observed. Very severe and unpleasant symptoms were experienced after the inoculations, but in Dr. Wright's letter to us, dated Oct. 6th, he informs us that the subsequent hours of misery and constitutional disturbances have now been reduced to a minimum by further experiments, and now all that is felt is a few hours' discomfort and a little local soreness, and equally good results in the blood are obtained with the diminished doses. The experiments showed that the patient's blood contains some substance which, although the bacilli of typhoid fever are not killed by it, yet exerts such a deleterious influence on them as results in the effectual protection of the patient against typhoid fever. Dr. Wright also wishes us to make public the fact that the resources of his laboratory have been placed at the disposal of the Maidstone authorities, by permission of the Director-General, Army Medical Service, and Surgeon-Major Semple has proceeded to the town with an ample supply of the "vaccine," enough for the whole population of Maidstone. The result of this proceeding will be watched with interest. We would take this opportunity also of protesting against the general public alarm which may accrue from statements made in the daily papers as regards the prevalence of typhoid fever in London and elsewhere. At this time of the year there is always an increase of this fever, and at the present time the numbers are not in excess of the average. The public should know that typhoid fever is not infectious in the same way as scarlet fever and measles, and that if frequent analyses of the water-supply are made and the excreta are disinfected no widespread diffusion of the disease need be feared.

THE "SPECTATOR" ON THE MEDICAL PROFESSION.

A WRITER in the *Spectator* has been thrown into some confusion by the Maidstone epidemic and led to express some doubts as to the "supposed capacity of science to deal with the problem of disease." To see hundreds of the inhabitants of a small, pleasant country town, with no deleterious local industry, with every condition favourable to health, within easy reach of the world's greatest city with all its manifold scientific agencies, stricken down by one of the most insidious diseases seems to stagger our excellent contemporary's faith in medicine. The writer quotes a very eminent man of science as saying—what he would not dare to say himself—"that three-fourths of medical science is little more than pure quackery." Surely this is rather a superficial and unscientific view of a great public calamity, and one which leads to putting the saddle on the wrong horse. Science, medical science, has taught for years that if communities do not protect their water-supply from contamination they will pay for it in three most definite forms—diarrhœa, cholera, and typhoid fever. This is an enormous lesson taught by science—by medical science—attention to which would have saved Maidstone from this calamity. Science in one sense will never go further, even in the pleasantest country town or in the greatest city with the greatest number of wise men in it. Science will not alter the properties of the typhoid poison, any more than it will alter the property of arsenic or of opium. The great thing is to avoid swallowing such things, and this requires only a little extra expenditure of money and of care on the part of communities and a little less selfishness on the part of water companies. Surely a comfortable community of 30,000 people at the end of the nineteenth century might be expected to take such obvious precautions for their own safety without troubling either Providence or the Local Government Board. We are sure that our contemporary will not on due consideration find any serious ground in the sad experience of Maidstone for reflecting on medical science, which really lights up the whole subject, dictates measures for public safety, and conducts

Digitized by Google

individual cases skilfully back to health. We are the more assured of this when we turn over a few pages of the same paper and find a most appreciative article on Sir J. Crichton-Browne's introductory lecture, eulogising especially the cheerfulness of the medical profession. The praise is just. Dr. Johnson said of Dr. Mead that he lived more in the broad sunshine of life than any man he ever knew; and the same holds of all true disciples of Æsculapius. They bring hope and relief. They "obviate" as Cullen said "the tendency to death." They eliminate disease on a large scale altogether from the employments and homes of men, and where they do not altogether succeed they fight it bravely when it comes. That they are successful in a large degree is shown by their very cheerfulness. If success were not their ordinary experience they would be of all men most miserable. And notoriously, as Sir J. Crichton-Browne says, and as our contemporary agreeing with him says, the contrary is the case.

THE PLAGUE IN BOMBAY FROM A FRENCH POINT OF VIEW.

DR. BONNEAU, medical officer of the first class in the French Colonial Service, who was deputed by the Governor of the French Possessions in India to make a study of the outbreak of plague at Bombay, has embodied the fruits of his mission in a lucid and instructive article which appears in the *Archives de Médecine Navale et Coloniale* for September. With regard to the genesis of the epidemic this writer comes to no positive conclusion. "It is certain," he says, "that the first cases occurred in a densely populated native quarter where the merchandise of the entire world is heaped up in the greatest profusion, awaiting distribution either by means of exportation or else internally to meet the industrial and commercial requirements of the country itself. The produce of China is there stored side by side with the cereals from Northern India. Was the disease imported from Hong-Kong, or did it travel with the wheat from the sub-Himalayan districts? This is a question that will probably remain unanswered." Certain observers have found an argument in favour of the Himalayan origin of the pestilence in the enormous mortality that took place among the rats infesting the go-downs where the wheat was lying, but Dr. Bonneau very effectively disposes of this theory by remarking that if more rats died there than elsewhere it was simply because they existed in greater number. The plague at first advanced slowly and insidiously, taking a long time to, as it were, put forth its roots, and Dr. Bonneau is quite satisfied that if energetic repressive measures had been adopted soon enough it could easily have been stamped out. Unfortunately, nothing at all was done by the municipal authorities until it was too late to summarily extinguish the innumerable foci of infection which had had time to establish themselves over the entire city. Mandevi, the quarter first contaminated, "consists of an agglomeration of unclean houses that are overflowing with filthy inhabitants. Not one single rule of hygiene is observed in this slum, where man and beast live together pell-mell amidst semi-darkness and respiring a heavy vitiated atmosphere. The sewers are not in working order, and on either side of the street close to the houses there are open drains about two feet in depth which, owing to defective flushing, are lined with an evil smelling deposit made up of vegetable and animal detritus." And yet, in spite of this shocking condition of things, the pestilence did not rage more severely in Mandevi than elsewhere, and when at last repressive measures were adopted it had almost completely disappeared from that quarter. The exodus that took place from Bombay was enormous. At the commencement of the present year it was calculated that upwards of 300,000 people had left the city, spreading themselves all over the peninsula. Old writers asserted that the plague never occurred south of a certain latitude, and as a matter of fact it has never crossed the equator; but great atmospheric heat cannot, as was alleged, be the sole cause of the exemption, because at the very time the epidemic was most severe in Northern India the temperature there was quite as high as it was in the south, which remained immune. Dr. Yersin's method of treatment is the only one of which Dr. Bonneau speaks approvingly. It is true that his results in Bombay were not so favourable as they had been in Hong-Kong, but this was owing to the manner in which the serum was prepared. In China it was obtained after the intravenous injection of living cultures, whereas in India the latter were dead and were injected subcutaneously. Yersin's serum is likewise, he considers, valuable as a prophylactic, but Dr. Bonneau was not at all impressed with the preventive quality of M. Haffkine's lymph, which he characterises as not only crude but dangerous. M. Haffkine's method, moreover, does not in his opinion possess the merit of novelty, having already been essayed by Ferran in Spain and Pfeffer in Germany.

THE DUTIES OF BOARDS OF GUARDIANS.

WE are of opinion that it is one of the duties of boards of guardians to grant relief and shelter to the vagrants, tramps, and such like persons who apply to them for relief. We are also of opinion that it is one of the duties of boards of guardians to administer that relief at the least possible expense to the ratepayers and consequently in a way which shall not tend to aggravate an evil which is one of the most difficult and pressing of our social problems. It is claimed, and claimed, we believe, rightly, that the Salvation Army by reason of its shelters has much to answer for in attracting to certain districts and neighbourhoods a class of persons who make mendicity a means of livelihood, and who, when "trade" is slack and they cannot get the necessary pence to swell the coffers of the Salvation Army, are obliged to seek the shelter of the casual wards and workhouses. Thus an increased burden is put upon the ratepayers, and the population of in too many cases an already overcrowded district augmented to an extent which, by reason of the character of that augmentation, is a menace to the public health. This being so it is surprising that a board of guardians should be found so apathetic to their responsibilities and duties as to attempt a procedure which encourages these pseudo-charitable institutions to carry on a work which is admitted by all who have rightly studied the question to be pernicious. From a letter in the *Times* from the pen of the Rev. J. E. Hand, assistant curate of St. Jude's, Whitechapel, it would appear, however, that the Bethnal-green board of guardians have adopted the practice of sending men to the Salvation Army Homes, for whom they pay 5*s.* per week per man. These men are troublesome to the guardians, hence they shift their responsibility to the Salvation Army at the ratepayers' expense. The Local Government Board do not appear to have sanctioned this practice (although we have not the letter written by the Local Government Board to the guardians on the subject before us), and had they done so we quite agree with the Rev. J. E. Hand that they would be "indirectly sanctioning the guardians to allow their 'loafer' paupers to enjoy immunity from any practical supervision by Poor Law authorities." Mr. Bramwell Booth has, of course, written a letter attempting to defend the guardians, but beyond correcting one or two errors in Mr. Hand's letter which are obviously the result of hurried writing—and the assistant curate of an East End district cannot be expected to find time hang heavily upon his hands—he practically makes no defence at all. Such statements as "Most of the men have remained in our employment

Digitized by Google

for some time, costing the guardians less with us than in the workhouse"; and "perhaps he (Mr. Hand) has not yet realised the responsibilities of a household and felt the bitterness of having to pay out of slender and hardly-earned income for the support in comparative luxury of idle wastrels whose whole business in life is to get through it at other people's expense," &c., are plausible; but, unfortunately for Mr. Booth, in this last sentence which we have quoted he gives his whole case away. It is these wastrels, as he very aptly calls them, who are the source of all the trouble; but whatever may be the inability of the guardians to deal with them there can be no shadow of a doubt that they should not be encouraged in this course of life. It is the shelters of the kind run by the Salvation Army which help to manufacture such kind of men, and as long as this class of people know that by suffering a little hardship—and hardship is second nature to them—they can obtain food and shelter to tide them over their vicissitudes, they will continue to live by the methods they have adopted. For this class of persons the shelters are nothing more than hotbeds for the forcing of mendicity. The Salvation Army shelters are not, and cannot be, in spite of anything which Mr. Booth may say to the contrary, under the control of the local authorities, as they do not come within the meaning of the Common Lodging Houses Acts, and it is monstrous that these places should have been allowed to attain the proportions they have. Surely it is time that the legislature should step in and place them under control, for until this is done, whatever steps may be taken to stamp out vagrancy in other directions, they will be circumvented by these so-called charitable institutions. We have nothing whatever to say against the motives of the Salvation Army, but their methods are often distinctly bad.

THE AWFUL BARGE STORY.

A GRUESOME story has appeared in the columns of several of our contemporaries about a barge full of hospital refuse, which was described as lying and leaking in the Thames during most of last week opposite the intake of one of the metropolitan water companies. The true facts of the case are as follows. The barge was loaded at the Lambeth Vestry wharf with ordinary house refuse. There is no truth in the statement that her cargo or any part of it consisted of hospital refuse, and in the interests of sterling fiction we should like to know who invented this report. The barge went up the river to discharge her cargo, but in consequence of its alleged origin no one would receive it. She was then allowed to lie on the foreshore until she became a nuisance, when an order was served on her by the Port of London Sanitary Authority "to abate." This order was complied with by the removal of the barge through Teddington Lock, out of the jurisdiction of the Port Sanitary Authority. By this time her story became known, or rather the untrue rumour about her contents became known, and she was refused facilities for discharge by everyone. She was then brought back into the jurisdiction of the Port Sanitary Authority when at once a fresh notice was served upon her "to abate." She was by this time leaking and her cargo was decomposing. The owner then brought her down to Chiswick and turned over the greater part of the cargo to a sailing barge which, with the original barge, was on Wednesday last towed down to the mouth of the river where the nuisance was thrown overboard. The main reason for serving a nuisance order was on account of the injury to the river from pumping out her bilge and not from any smell or effluvium from the material, which had been freely treated with chloride of lime under the supervision of the Medical Officer of the Port, Dr. W. H. Collingridge. We understand that the owner of the barge, having practically refused to take steps to abate the nuisance, has been summoned at the West London Police Court. There is no doubt that he did not show a ready compliance and that his inaction might have been perilous to the community, but we can understand his feelings of helpless exasperation at the treatment that he received on the river-bank and the lying rumours concerning his cargo.

THE OUTBREAK OF TYPHOID FEVER AT UNIVERSITY COLLEGE HOSPITAL.

IN the course of the last ten days several cases of typhoid fever have occurred amongst the nurses and maids at University College Hospital. In all about eighteen have been attacked. A temporary dining-room had been provided for them in the course of the summer when certain houses in which they had been previously accommodated were pulled down on account of the re-building of the hospital. The water which had been used for drinking in this room, instead of being taken from the main as is usual throughout the hospital, was drawn from a cistern which became contaminated. The defect has now been remedied, but it has been thought best to provide another dining-room in a different part of the building. No cases have appeared amongst the patients in the wards, the sisters, or the resident officers. Up to the present time all the cases are doing well.

RECURRENCE OF HEPATIC ABSCESS AFTER INCISION AND APPARENT RECOVERY.

DR. PAUL REBREYEND reports[1] an interesting case of recurring hepatic abscess in an old soldier, aged forty-seven years. The patient had suffered from dysentery in Algeria in 1874, but it was not until he quitted the army five years later that he began to feel pain, accompanied by a sensation of weight, in his hepatic region. These somewhat vague symptoms recurred at intervals during the next three or four years, each recurrence necessitating the interruption of his work for a few days; and in 1883 he for the first time became aware of a swelling which in the course of about a fortnight developed into a well-defined epigastric tumour. For this he was treated in the Hôtel-Dieu by Professor Le Fort, who performed aspiration three times at intervals of a week, injecting tincture of iodine on the last two occasions. With regard to the character of the matter evacuated the patient was quite positive. At no stage did it resemble hydatid fluid, having from the beginning been reddish-brown in colour and so thick that it was only with difficulty it could be made to flow through the cannula. A week after the last aspiration, as the tumour had again filled and was larger than before, a vertical incision five centimetres long was made slightly to the left of the median line, and in ten days, cicatrisation being firmly established, the patient was discharged completely recovered. Six months later, however, he experienced a return of his former malaise, the pain and heavy feeling lasting several days, but his medical attendant administered quinine and a few doses of calomel, and the trouble seemed to pass away definitively. It was not until fourteen years had elapsed that he again sought treatment on account of his hepatic affection. A fortnight previously, without any obvious cause, he was seized with pain in his epigastrium, and soon a tumour as large as an orange made its appearance at the old site. On examination the liver was found to be small and retracted, hidden under the false ribs but not encroaching on the lung. There had been no jaundice, vomiting, or diarrhœa, and his appetite was good. During the interval the patient's general health had remained satisfactory; he had lost neither flesh nor strength,

[1] Duplay's Archives for August, 1897.

Digitized by Google

and his renal excretion had been normal. On June 13th, 1897, Dr. Marchand operated at the Saint-Louis Hospital, reproducing his predecessor's incision, but prolonging it slightly downwards. The tumour contained yellowish-green, grumous pus, and was firmly adherent to the parietal peritoneum. Its walls were very thick and fairly smooth internally, but the contained cavity was somewhat irregular in shape. The pus, examined under the microscope and also by culture on gelose, was pronounced to be sterile. Hooklets and other relics of the echinococcus were carefully searched for but with negative results. In conclusion Dr. Rebreyend gives it as his opinion that the case is the first on record in which recurrence of an hepatic abscess occurred after operative interference followed by such a long interval. The cause or causes which led to the recurrence are, however, still to seek, but the fact that the pus evacuated at the second operation was sterile is greatly in favour of the view that the second abscess was not of recent formation; the thickness of its walls also points in the same direction, so that we are justified in thinking that it had formed a long time, probably years, previously—perhaps it had commenced immediately after the first operation. The sudden appearance of the abscess may easily have been due to a little fresh exudation into it caused perhaps by some slight unnoticed trauma and the increase in size may have sufficed to break through some fascia which had held it down, so that it formed an obvious swelling.

CHEWING GUM.

AN inquest was held on Oct. 6th at Lincoln upon the body of a child, aged seven years and eleven months, who died after eating "chewing gum." The sweetmeat in question was labeled "for chewing only" and "this is not to be eaten." After hearing the medical evidence the jury returned a verdict "that death was due to peritonitis of which they were unable to say the cause. At the same time the foreman stated they would like to say that in their opinion the sale of chewing gum should be strictly prohibited and shopkeepers asked to refrain from selling it." This last request seems to us to be superfluous in view of the preceding words, and besides to ask anyone to refrain from selling a harmful substance is silly. The right course is to pass a law to make anyone who sells stuff of this kind liable to a heavy penalty. We refer in our leading columns to this subject, but it is our firm opinion that quack medicines and the like will never be got rid of until such practices are made unprofitable. A fine of 10*s.* for adulterating foodstuffs is absurd, and in addition to increasing the fine by at least a hundred times the recommendation of the Select Committee ought to be enforced as to the convicted person publishing a notice of conviction in his place of business. What chewing gum is made of we do not know, but it is probably similar to that delectable mixture "chocolate chumps," which consist largely of paraffin wax and are quite indigestible.

THE SYMPTOMS OF CONGENITAL DIAPHRAGMATIC HERNIA.

CONGENITAL diaphragmatic hernia is rare; much more rarely is it the subject of clinical observation. The following case, published in the *Archives of Pediatrics* (New York), September, 1897, is therefore important. A healthy child, aged one month, was attacked by indigestion and colic, attended with frequent vomiting and quickened, laboured breathing. The pulse was from 130 to 160 and the respirations were from 60 to 80, with inspiratory recession. Percussion resonance of the chest was accentuated and the tympanitic sound of the abdomen was transmitted high into the thorax. Vesicular breathing was heard everywhere, but it was much more feeble than normal. The vomiting ceased in a day or two, but the laboured breathing continued. On the sixth day there was an exacerbation, and a frightful picture of Henoch's asthma dyspepticum was presented. After a short spell of crying the child suddenly became blue in the face and hands; he made violent respiratory efforts with slight success; his pulse was not perceptible; the extremities became cold, and cold perspiration dripped from the face. Active movements of intestinal gas could be heard. Warm mustard cloths were applied, but the paroxysm was not relieved until it had lasted an hour. He improved during the next few days, losing the inspiratory recession of the chest. But another asthmatic paroxysm occurred on the ninth day in which the ensiform cartilage was retracted almost to the spine and twitchings of the muscles of the face and arms occurred. After this other attacks took place from time to time, but they gradually diminished in number and intensity. They generally passed off with an escape of gas from the stomach and intestine. Gas could be felt moving in the abdomen and sometimes over the whole body. At the end of six weeks, when the child was apparently quite well, a moderate paroxysm occurred, in which he died. At the necropsy a deficiency was found in the diaphragm on the left side. The left pleural cavity was filled by the whole of the small intestine except the first two inches of the duodenum, the cæcum, the ascending, transverse, and part of the descending colon, together with the pancreas. The left lung was compressed into a small space. The heart was situated to the right of the median line deep in the mediastinum. During life the case was diagnosed by the writer, Dr. Booker, of Johns Hopkins University, and by Dr. Osler as asthma dyspepticum. A correct diagnosis of these cases is scarcely ever made.

YELLOW FEVER IN THE UNITED STATES.

YELLOW fever is still prevalent in the southern part of the United States, and if the sensational accounts published daily in the New York lay papers can be credited the condition of affairs in the Mississippi States is indeed lamentable. Happily, these are without a doubt highly coloured reports, and it would seem, judging from the American medical journals, that the epidemic is of a mild type and likely when cold weather sets in to disappear entirely. The circumstance that the outbreak has occurred in the autumn rather than in the spring must be regarded as fortunate, for it is more than probable that if the germs had been conveyed to the Gulf shore in the early part of the year a far-spreading and severe epidemic would have been the consequence. The work of combating diseases of an epidemic nature falls on the Marine Hospital Service, and most effectively have they discharged this duty. The appearance of yellow fever so soon after the announced discovery of the germ of that disease by Sanarelli is a somewhat peculiar coincidence. Another feature of the outbreak is the extraordinary panic that has seized the inhabitants of the districts, not only within the infected area, but of districts far outside. In fact, the inhabitants of the region in which the disease is raging appear to have kept calm in comparison with these outsiders. Every town and village in Alabama and Mississippi has established what a well-informed correspondent in the district has termed in a communication to us a "shot-gun quarantine." Although the disease has been officially declared to be yellow fever, and doubtless is, yet several medical men in New Orleans and the adjacent country stoutly deny the assertion, but say that it is a form of malaria or what is known in India as sun fever. Many of the resident health officers, who, of course, support the contention that it is yellow fever, say that the disease is as yet in an inchoate form; and Dr. Alfred Duperier, a southern health official,

Digitized by Google

draws attention to the fact that the worst epidemic of yellow fellow ever known in America, that of 1853, came in, like this year, with dengue, and that for some time it was difficult to distinguish between the two. Dr. Duperier goes further than this and states his belief, in which he is supported by the late Dr. Austin Flint (in his work on the Practice of Medicine), that these diseases are germane. Excellent authorities, however, believe that when frosty weather sets in the disease will disappear. In connexion with Sanarelli's discovery it is interesting to note that the majority of medical men in the United States are coming round to a belief in its genuineness.

PANCREATIC LITHIASIS.

AN abstract of the following case, published by J. Nicolas, appears in a recent number of the *Revue des Sciences Médicales*. A man, aged forty-seven years, entered a hospital in consequence of an affection which began suddenly two and a half months previously and was characterised by loss of strength, anorexia, and violent epigastric pains of an intermittent and paroxysmal type. Very abundant melæna, amounting to a litre, took place, which relieved him. This occurred again. There was no diarrhœa. The signs of pancreatic diabetes showed themselves. He passed 179 grammes of sugar per day. Six months after the onset of the disease he died from caseous pneumonia. At the necropsy the duct of Wirsung was found to be obstructed by fifteen or twenty calculi embedded in the walls. The duct communicated with a large purulent cavity which occupied a third of the pancreas, which was sclerosed. The cavity opened into the duodenum by a fistula. Probably from its walls the blood of the melæna had issued.

DISINFECTANT SOAPS.

AN important investigation into the relative antiseptic properties of a number of commercial and medicated soaps has recently been made by Dr. S. Rideal and the results are of undoubted interest. It is not surprising that he finds that many so-called disinfecting soaps are quite worthless as germicides. He points out the incompatible character of many of the antiseptic agents which have been incorporated with soaps for this purpose. Boracic acid, for example, is converted into sodium borate, which possesses little antiseptic power. Metallic salts are precipitated and disappear in an insoluble form from the water in the curd. Oleates of the metals are similarly inert. Dr. Rideal suggests that the metallic oxides dissolved in soda or potash might give better results. Mercuric iodide dissolved in potassium iodide to form potassio-mercuric iodide appears to be an excellent antiseptic, which is, moreover, quite compatible with soap basis. A soap prepared in this way containing 3 per cent. of iodide of mercury when tried with vigorous growths of both the bacillus coli and the staphylococcus pyogenes aureus inhibited growth, and rendered the liquid sterile from the time of its addition. Formalin however, compares very favourably with these results, since soap containing only 0·4 per cent. of formalin effected sterilisation within thirty minutes of the time it was added. The experiments were conducted with a 2 per cent. solution of the soap. Dr. Rideal regards the disinfectant power of the essential oils as having been much over-rated, and in a series of experiments in which carbolic and clove oil soaps were tried, it was found that these had an antiseptic action equal to, but not exceeding, ordinary curd soap. In the same series of experiments the biniodide soap proved superior, while carbolic soap containing three pounds of phenol to the hundredweight of soap proved for practical purposes to be of little avail. The inquiry is of the greatest value, not only in connexion with the uses of so-called antiseptic soaps in medical and surgical work, but also in connexion with the popular belief that the use of many so-called antiseptic or disinfectant soaps necessarily guarantees immunity from infectious diseases.

THE HOSPITAL REFORM ASSOCIATION.

A CONFERENCE has been arranged by the Hospital Reform Association to take place at St. Martin's Hall, Charing-cross-road, London, on Thursday, Oct. 21st, at 4.30 P.M. The Earl of Stamford will preside, and Mr. Timothy Holmes, Sir William Broadbent, Mr. Victor Horsley (the newly elected Direct Representative on the General Medical Council), Dr. Lovell Drage, Dr. Isambard Owen, Sir Henry Burdett, and Mr. C. S. Loch have promised to attend and speak. It has been arranged to discuss the administration of medical relief in the out-patient and casualty departments of hospitals and dispensaries, and the association suggests that the conference should deal more especially with (1) subscribers' letters, (2) patients' payments, (3) limitation of the number of new cases, and (4) the means to be employed to restrict relief to fit and proper cases. Hospital managers, members of the medical staffs of hospitals, general practitioners in medicine, and representatives of supporters of hospitals are invited to attend and join in the discussion, Mr. T. Garrett Horder, Cardiff, the hon. secretary of the Hospital Reform Association, informs us that the conference will adjourn at 6.30 P.M. and meet again at 8 P.M., so that ample time will be given for the meeting to hear the views at length of many speakers. Mr. Horder will be glad to receive donations towards defraying the expenses of the meeting.

THE LONDON COUNTY COUNCIL, TYPHOID FEVER, AND WATER SUPPLY.

THE zeal of the London County Council in its interest to guard the public health is of course worthy of commendation, but we imagine that its recent decision to refer to the Public Health and Water Committee the question for them to inquire and report upon as to whether the causes which have led to the typhoid fever epidemic in Maidstone have any parallel in the conditions of the London water-supply, and what steps, if any, should be taken to prevent the propagation of the disease in London, will lead to an answer which has long been known before. To commence with, the source of supply in Maidstone is from wells, while the metropolitan supply is, with the exception of the Kent Company, which is but a small fraction of the whole, derived from flowing rivers, the Thames and the Lea. Further, the water supplied to London is with the same exception filtered. There is no such intercepting purifying process at Maidstone. This is a fact alone which should reassure the London public. The extraordinary purifying effects of sand filtration are well established, and it is not too much to say that so effective is this filtering method that the filtered water is again and again found to be sterile—that is, free from organisms, whether pathogenic or non-pathogenic. It is even doubtful whether pathogenic organisms occur in the water drawn at the intakes since the flow of a river is very inimical to the life of the disease germ, especially when associated with a countless number of harmless organisms. The practical absence of water-borne diseases like typhoid fever and cholera in London during the last thirty years is undoubtedly due to the efficiency of sand filtration, and it is of vital importance that this efficiency should be always maintained. In such a case the London water-supply that is derived from the Thames and the Lea may be depended upon. What we should like the County Council to do is to take some action which shall result in the appointment of a competent authority, whose duty it shall be to inspect and control the great filtering

Digitized by Google

processes at the waterworks of the several companies. How important the efficiency of sand filtration is may be judged from the fact that it is this mainly which has kept London water-drinkers free from disease. Then let this efficiency be doubly secured by a system of independent control and inspection.

MEDICAL AND SCIENCE STUDENTS AND THE INDIA CIVIL SERVICE.

WE may briefly call attention to a communication from a correspondent in connexion with this subject which appears at page 1011 of the present number of THE LANCET. Concerning the high reputation and character which the India Civil Service deservedly enjoys and the opening and opportunities it affords to men of ability and culture for distinguishing themselves there can be no doubt; but it must be borne in mind that ability and culture of a superior kind are indispensably requisite on the part of intending candidates, for the examination is of a high standard and the competition is severe. We quite concur with our correspondent in what he says about the stress and hardship of competition in the medical profession in this country, and valuable appointments and promising careers for medical and science students outside the profession are therefore to be well considered and welcomed. Whether this career is within the reach or not of such students, and whether the character and scope of the India Civil Service examination be such as to offer them fair and reasonable chances of success we cannot say, but our correspondent declares that they are, and the special object of his communication is to show this to be so. Hitherto Oxford, Cambridge, and Dublin University men running on classical or mathematical lines have mainly been the successful competitors for these appointments, and there has been a virtual absence of candidates who have devoted themselves to natural science. The subjects embraced by the India Civil Service examination give it an elevated and broad standard, and that the mere preparation for it tends to put a man on a high intellectual plane by the wide and accurate reading and sound liberal culture demanded of him is certain, so that even the unsuccessful student will have little or no cause to regard his studies as wasted time, whereas if he is successful he will enter on a career that is lucrative and well worthy of his ambition.

PSYCHRO-ANÆSTHESIA.

IN the last number of *Brain* Dr. Leonard Guthrie has described under this name a curious case of sensory disturbance. The patient was a bricklayer, aged fifty-two years, who was seen in 1894 and complained then, as he has continued to do since, of a sensation of painful coldness affecting at first the right leg, but later also the arm on the same side. He had always been in good health since 1892, but when kneeling at work his right knee became locked. In August, 1893, he fell, and effusion took place into the joint. He was then also found to have a loose cartilage in the joint. He said that when the coldness first came on it seemed as though his foot was placed on ice in the hollow of the foot, but now it was all over the foot, and the coldest pain came from the roots of the toes. He described the sensation in the foot and leg as if a number of insects were trying to pass each other and could not. The foot was most comfortable in a hot bath or in bed, but he could not bear anything to touch him on the leg besides the bed-clothes. The knee-jerks were active and equal on the two sides and there was no unsteadiness. Tactile sensation was perfect, and pin-pricks were recognised readily and accurately. He also appreciated heat and cold, but application of cold to the right leg was distressing, while that of heat was agreeable. There was no difference in the temperature of the limbs and no evidence of trophic disturbance; but the whole of the right lower extremity was flabby, and the thigh on this side measured an inch less, and the calf three-quarters of an inch less, than the corresponding parts of the opposite leg. The sensations of cold were not confined to the area of distribution of particular nerves. Dr. Guthrie remarks that he has adopted the term "psychro-anæsthesia" used by Silvio to describe symptoms somewhat resembling those of his patient. "Meralgia paræsthetica" is a term used by Roth of a similar condition, and the subject has also received attention from Bernard, Escat, Osler, Hirsch, and Weir Mitchell. After discussing the various possible conditions which might give rise to the symptoms in this case, Dr. Guthrie is inclined to think that the most likely condition is one of syringomyelia in which the function of the posterior commissure is perverted but not destroyed, and he reports that so far all the ordinary remedies have failed to afford any relief.

DAMAGES FOR NEGLIGENCE IN BELGIUM.

AN action has recently been tried in Liège in which a member of a medical aid society who had been injured sued the medical officer for damages on account of non-attendance. It was stated that he was repeatedly sent for, but did not visit the plaintiff for six days, and no explanation of this negligence appears to have been offered. It was not shown that the plaintiff's recovery was as a matter of fact retarded as another medical man was called in, but the court considered that the plaintiff had to bear physical and moral pain to an extent which he would not have had to endure had he received immediate medical attention and as a solatium awarded him 200 francs. In commenting upon this case the *Scalpel* points out that, quite apart from the merits of this particular instance, the reason given for this award appears to open up a new terror for the medical officer of a club, for whenever he may be prevented from attending immediately it may always be possible to affirm that the patient has had to endure "physical and moral pain" which might have been allayed by earlier attention, and so is entitled to substantial damages. Indeed, the adverse legal decisions and the growing exactions of the clubs have led the *Scalpel*, which may be regarded as giving expression to the feelings of the profession in Belgium, to declare that there is only one way of solving the difficulty, and that is by medical men refusing all contract appointments and insisting on clubs and medical aid societies paying a fee for each attendance.

OPENING OF THE MEDICAL SESSION AT ST. VINCENT'S HOSPITAL, DUBLIN, AND THE ARMY MEDICAL SERVICE.

THE opening of the medical session at St. Vincent's Hospital, Dublin, under the presidency of Sir Christopher Nixon, on the 5th instant, was largely attended. Dr. Cox delivered the address on the occasion, and mainly took for his theme the genesis and development of the Army Medical Service as it is at present and as it should be. The lecturer, in the course of an eloquent address, alluded to the distinguished part which the medical service had always played in the history of the army and vindicated the claims of medical officers to have their grievances considered and redressed. The medical service, he declared, required to be advanced another step and to be constituted, like the Royal Engineers, into a Royal Corps, and its officers to have purely military rank and titles with limited power of command, but absolute within its own sphere. Dr. Cox, in the course of his address, after alluding to many conspicuous services rendered by medical officers, proceeded to cite some illustrations of the treatment which had been

Digitized by Google

accorded to them by some high military authorities, attributable apparently to a dominating and aggressive spirit of militarism. Sir Christopher Nixon and Sir William Thomson, President of the Royal College of Surgeons in Ireland, who proposed a vote of thanks to Dr. Cox, followed with some speeches to a similar effect. It is quite clear that the Army Medical Service owing to its present unpopularity has ceased to attract a sufficient number of candidates to fill its vacancies, and it is not likely to be otherwise until it is authoritatively known what steps are proposed to be taken by the Government in the matter. The sooner the new warrant is published the better for all concerned.

THE TREATMENT OF GENERAL SUPPURATIVE PERITONITIS.

RECOVERY after laparotomy for suppurative peritonitis is rare. A new method of operating, described by Dr. J. M. T. Finney in a recent number of the Johns Hopkins Hospital *Bulletin*, which proved successful in five consecutive cases therefore demands attention. He attributes the failure of previous methods to insufficient removal of the infectious exudation. The observations of Pawlowsky show that in purulent peritonitis the lymph channels are choked with bacteria and inflammatory products. The naturally great powers of absorption of the peritoneum are much diminished and it is unable to dispose of the inflammatory products. Dr. Finney operates as follows. A sufficiently long incision to admit of easy access to all parts of the peritoneal cavity is made. The coils of small intestine are quickly withdrawn, beginning with the one that is perforated. All or as much as is necessary of the small intestine is placed outside the abdomen and covered with warm gauze or towels. The peritoneal cavity is then thoroughly and systematically wiped out with large pledgets of gauze wrung out of hot salt solution, paying particular attention to the pelvis. In some cases it may be well to flush with warm salt solution, but this is rarely necessary. Next the small intestine is systematically examined loop by loop while still outside the abdomen and cleansed by wiping. It is necessary to wipe with considerable force at times in order to remove adherent flakes of partly organised lymph. Success depends on the thoroughness with which this is done. The cleansing process is facilitated if the wiping of the coils is carried on under a constant irrigation of warm salt solution. The intestines are replaced with the damaged or sutured coil the most superficial, in order that it may be the better drained by being packed around with gauze if necessary. The abdominal wound is tightly closed, leaving just room enough between two sutures for a gauze drain. If there are any evidences of distension or pain Paquelin's cautery should be thoroughly applied to the abdomen, and the bowels should be moved early by calomel in repeated doses followed by salts and a turpentine enema. To ensure success, the operation should, if possible, be performed within a few hours of perforation. In Dr. Finney's five successful cases the peritonitis was secondary to typhoid perforation in one and to appendicitis in four. He operated unsuccessfully in one case of appendicitis, but the patient was *in extremis* at the time of the operation, which was only undertaken as a forlorn hope.

ON the recommendation of the General Purposes Committee the London County Council have approved the appointment of Dr. Clowes to the post of chemist in the place of Mr. Dibdin, who resigned some months ago. Dr. Clowes (D.Sc. Lond.) was the professor of chemistry at the University College, Nottingham, where he was very popular, and where he has carried out some important work of investigation. His name may be remembered chiefly in connexion with the introduction of a method for the accurate detection of the quantity of explosive gas in the air of coal mines.

IT has been decided to hold a dinner of the members of the Society of Medical Phonographers to congratulate Sir William Gowers on the recent honour which Her Majesty has been pleased to confer upon him. The dinner is to be held on Nov. 25th, and Sir William Broadbent, who ever since the foundation of the society has been one of its warmest friends, has expressed his willingness to take the chair on the occasion. Inquiries should be addressed to Mr. L. E. Creasy, 1, Windsor-road, Ealing, or to Dr. James Taylor, 49, Welbeck-street, W.

A PATHOLOGICAL meeting of the Neurological Society of London will be held at 11, Chandos-street, W., on Oct. 28th, at 8.30 P.M. Members wishing to make communications are invited to let the secretaries, Dr. F. W. Mott, F.R.S., and Dr. J. S. Risien Russell, know as soon as possible, and are requested to send very short abstracts dealing with the salient features of their communications.

THE annual public night in connexion with the Medical Society of University College, London, will be held on Wednesday, Oct. 20th, when an address will be delivered by Dr. W. B. Ransom on "Vis Medicatrix Naturæ." The chair will be taken at 8 P.M. by the President, Dr. G. B. Hunt. There will also be an exhibition of Roentgen rays, instruments, slides, &c.

THE autumn dinner of the Irish Medical Schools' and Graduates' Association will take place at the Café Monico, Piccadilly, on Nov. 2nd, at 7.15 P.M. Professor Alexander Macalister, F.R.S., will preside, and the association will entertain Field-Marshal Lord Roberts, V.C., G.C.B.

THE Roentgen Society will hold its opening meeting at St. Martin's Town Hall, London, W.C., on Nov. 5th, when the presidential address will be delivered by Professor Silvanus Thompson. There will be an exhibition of Roentgen apparatus, photographs, and methods.

THE Leprosy Conference which has been sitting during the week at Berlin has had a full programme both scientific and social. We may expect as a result of its deliberations some authoritative and practical conclusions concerning the pathology and treatment of leprosy.

DR. COUPLAND'S report to the Royal Commission on Vaccination concerning the outbreak of small-pox in Leicester in 1892–1893 was issued on Wednesday last as a Parliamentary paper.

MR. E. H. DOUTY, M.B. Cantab., has resigned the office of assistant surgeon to Addenbrooke's Hospital, being obliged to leave Cambridge by the state of his health.

WE draw the attention of our readers to an advertisement announcing the proposed formation of a whist club to which members of the medical profession will be elected under favourable circumstances. Too much whist is as bad for a medical man as for anybody else, but a little whist in the evening would be a very useful prescription for many over-worked practitioners.

PATHOLOGICAL SOCIETY OF MANCHESTER.—At the annual meeting of the above society held on Wednesday, Oct. 13th, 1897, the following gentlemen were elected office-bearers for session 1897–98:—President: Mr. C. E. Richmond. Vice-Presidents: Dr. H. A. G. Brooke and Dr. R. B. Wild. Treasurer: Dr. T. A. Helme. Secretary: Dr. T. N. Kelynack. Committee: Dr. A. Brown, Mr. J. Collier, Dr. J. E. Platt, Dr. E. T. Milner, Dr. E. S. Reynolds, Mr. J. W. Smith, Mr. W. P. Stocks, and Dr. R. T. Williamson. Auditors: Dr. F. C. Moore and Dr. W. E. Fothergill.

A METHOD OF PRECISE LOCALISATION AND MEASUREMENT BY MEANS OF ROENTGEN RAYS.

BY JAS. MACKENZIE DAVIDSON, M.B., C.M. ABERD.,
AND
W. S. HEDLEY, M.D. EDIN.

A SKIAGRAPH is a shadow upon one single plane of objects that may be situated on various planes. The shadows thus obtained indicate the presence of an object, but give no correct idea of its form or size or relative position. The picture has no relief. It is indefinite and apt actually to be misleading. It is not surprising, therefore, that in the case of foreign bodies embedded in the tissues operative failure has often followed a too exclusive reliance upon the indications of the Roentgen photograph. In fact, the latter has hitherto been accepted by the prudent surgeon as evidence of the presence only of a foreign body in a part and not as reliable evidence of its position or size. It has long been evident, therefore, that some method must be devised for arriving at the size, shape, and position of the real object.

The present writers have lately worked out a method which is fully able to accomplish this. Many suggestions have been made from time to time as to varying the position of the tube or of the object and taking two or more pictures and estimating by triangulation the position of the foreign body. There are many practical difficulties in the way, and none of these suggestions have hitherto resulted in any method sufficiently definite to meet the actual requirements of practice. It occurred to one of us (Dr. Mackenzie Davidson) to actually work out the position of the foreign body by means of fine silk threads so arranged as to represent the actual path of the x rays which produced the negatives. He then constructed the apparatus to carry out the method, which is as follows. Two wires at right angles to each other are placed upon the photographic plate, film, or paper. The Crookes's tube is then placed with its anode at a measured distance from the plate and exactly perpendicularly to where the wires cross. The tube is fixed in a holder which slides in one plane. Further, one of the cross wires must be in exactly the same plane as that in which the tube is to be displaced. The wires being painted over with some pigment the part to be photographed is placed on the plate and carries with it a mark of the cross wires. The tube is then displaced to a measured distance to one side of the perpendicular and an exposure given, then to a corresponding point on the other side of the perpendicular and another similar exposure given. The resulting negative shows double images from the two different points of view. A further precaution is necessary—viz., to mark one quadrant of the plate and the corresponding quadrant on the patient's skin.

The negative having been developed, fixed, and slightly washed is at once placed on a horizontal stage illuminated from below by a suitable reflector (an arrangement similar to a re-toucher's desk). The negative may be placed with the gelatin surface upwards, or downwards if the glass is not too thick. In the case of celluloid films it is most convenient to place them downwards. The negative is adjusted so that a perpendicular dropped from a notch in a horizontal scale falls upon the point where the shadows of the wires cross. On each side of it another notch is made at the exact distance and height that the anode of the Crookes's tube occupied in the two exposures. A fine silk thread is then passed through each lateral notch and a small lead counter weight is attached to one end of each thread, while the other is passed through the eye of a fine needle. The needle is weighted with lead so that its eye lies flat on the surface of the negative. In short, these two silk threads represent the path of the x rays, so that if each needle be carefully placed upon a corresponding point in each shadow it follows that the point where these threads cross marks the position occupied by the corresponding part of the actual object. Further, its distance can be measured perpendicularly from three planes—from the horizontal which gives its depth and from the two planes represented by the shadows of the cross wires. By measuring any other desired corresponding points the precise size, position, and direction of the object can be determined, and remembering that the cross wires have left their mark on the patient's skin we can at once from these data give the surgeon all the information he can possibly desire. One of us (Dr. Hedley) has suggested that instead of displacing the tube, two tubes be used and a simultaneous exposure given.

It appears to us that this method has the following advantages: (1) the exact localisation can be completed a few minutes after the photograph is taken; (2) it can be used by anyone without recourse to any mathematical formulæ; and (3) it will be useful for measuring bony surfaces and cavities—e.g., the pelvis. The method has been fully tested on the living subject as well as on artificial models,[1] and has proved very accurate and reliable. Messrs. Curry and Paxton, 195, Great Portland-street, have made an apparatus to Dr. Mackenzie Davidson's design by means of which the method can be carried out conveniently, accurately, and quickly.

CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual Calendar has just been published by the Council of the College. It shows that there are 1191 Fellows on the roll of the College (as compared with 1175 last year), of whom 1023 obtained the Fellowship by examination, 15 were elected as Members of twenty years' standing under Section 5 of Cap. 15 Vict., 151 are Fellows by election, and 2 are *ad eundem* Fellows. There are 17,333 Members (as compared with last year's total of 17,102) and 590 Licentiates in Midwifery, the examination for this Licence having been discontinued since 1876. The Licentiates in Dental Surgery are stated to number 1186 (or an increase of 94 over last year) and the Diplomates in Public Health to number 282.

During the past collegiate year 9 candidates presented themselves in elementary physiology, 8 of whom passed and 1 was referred; 387 candidates presented themselves in elementary biology, of whom 246 passed and 141 were referred. Of 503 candidates who presented themselves in chemistry 300 passed and 203 were referred; in materia medica, of 98 candidates 59 passed and 39 were referred; in practical pharmacy, of 309 candidates 228 passed and 81 were referred.

The proportion of the fees paid by candidates for these examinations receivable by the College amounted to £1933 11*s.* 6*d.*, the examiners elected by the College receiving £195 5*s.* The examiners in elementary biology are appointed by the Council of the College, those in elementary physiology in conjunction with the Royal College of Physicians of London, and those in chemistry, materia medica, and practical pharmacy by the Royal College of Physicians of London, under the scheme for an Examining Board in England.

The examiners in anatomy and physiology for the Second Examination are appointed in conjunction with the Royal College of Physicians of London; they have conducted the Primary Examination under the Old Regulations as well as the Second Examination of the Examining Board; 715 candidates presented themselves for examination in anatomy, of whom 349 passed and 366 were referred; 702 presented themselves in physiology, 346 of whom passed and 356 were referred. The proportion of fees paid by candidates to the College for these examinations amounted to £3219 16*s.* 6*d.*, the examiners appointed by the College receiving £1159 16*s.*

The Board of Examiners in anatomy and physiology for the diploma of Fellow, elected annually by the Council of the College, held two meetings for the examination of 193 candidates, of whom 59 passed, whilst 134 were referred. The fees paid by candidates amounted to £1207 10*s.*, of which the Board received £772.

The Court of Examiners, ten in number, are elected by the Council from the Fellows of the College only for a period of five years. They conduct the Third or Final Examination in surgery of the Examining Board in England as well as the Second or Final Examination for the diploma of Member

[1] As an extreme instance it may be mentioned that a No. 5 shot has been accurately localised in a mass of paraffin made opaque by lamp-black. The shot was reached by a single needle puncture at the estimated depth before being cut down upon.

Digitized by Google

under the Old Regulations and the Pass or Final Examination for the diploma of Fellow. During the past collegiate year the Court held two examinations for the Fellowship and four for the Membership. At the former there were 96 candidates, 50 of whom passed; 43 were referred for six months and 3 for one year. For the Membership 783 candidates presented themselves in surgery, of whom 493 passed and 290 were referred. The fees paid by candidates for these examinations amounted to £10,365 14*s.*, and the fees paid to the Court of Examiners and the examiners in midwifery amounted to £5172 19*s.* The examiners in medicine under the scheme for an examining board in England are elected by the Royal College of Physicians of London. Of 794 candidates examined 489 passed and 305 were referred. The examiners in midwifery are appointed in conjunction with the Royal College of Physicians of London and have examined 932 candidates, of whom 576 passed and 356 were referred.

The Board of Examiners in dental surgery have held two meetings for the examination of 141 candidates, 98 of whom received the Licence and 43 were referred. The fees received from candidates amounted to £1029, of which the Board received £592 4*s.*

The examiners in public health appointed in conjunction with the Royal College of Physicians of London examined 43 candidates in Part I., 32 of whom passed and 11 were referred; in Part. II. out of 51 candidates 29 received their diplomas and 22 were referred. The fees received by the College for both parts of the examination amounted to £222 12*s.*, the examiners receiving £141.

With regard to the finances of the College, it appears that the income from all sources amounted to £28,975 7*s.* 3*d.*, the largest item being derived from the fees paid by candidates for the diplomas of the College—viz., £17,978 4*s.*—the next largest being from dividends on the Erasmus Wilson bequest, £4885 4*s.* 10*d.*; rents from chambers adjoining the College produce £750; investments, £797 6*s.* 10*d.*; hire of rooms, sale of questions, &c., at Examination Hall, £701 5*s.* 1*d.*; incidental receipts at the College, £231 13*s.* 3*d.*; receipts from trust funds, £290 2*s.* 8*d.*; dividends from sinking fund for Savoy Estate, £6 3*s.* 3*d.*; expenses, repayable by Metropolitan Asylums Board at Midsummer, 1896, £282 0*s.* 6*d.*; fees retained for candidates, £404 5*s.*; amount paid by the London County Council on taking over Lincoln's-inn-fields, £1162 19*s.* 5*d.*; balance at Midsummer Day, 1896 (including half-balance Goldsmiths' Company Research Grant), £1486 2*s.* 5*d.*

The expenses for the year amounted to £27,184 12*s.* 2*d.* (leaving a balance at the bankers, including half Goldsmiths' Grant, of £1790 15*s.* 1*d.*), the largest item being (as in the receipts) in connexion with the examinations—examiners' fees, £8033 14*s.*; half expenses of Examination Hall for the purposes of examinations, £4151 13*s.* 2*d.* (this amount includes rent, rates, taxes, fuel, and light, which absorb the no small amount of £2087 1*s.* 4*d.*); expenses of Fellowship and Dental Examinations, £376 15*s.* 1*d.* Half expenses of the Scientific Laboratories on the Victoria-embankment amount to £689 12*s.* 3*d.* (this amount does not include rent, rates, taxes, fuel, or light). At the College rates, taxes, and insurance stand at £1314 19*s.*; extraordinary expenses—i.e., reconstructing lecture theatre, Hunterian festival, &c.,—£1003 0*s.* 8*d.*; alterations and repairs, £329 11*s.*; fees to members of the Council, £236 5*s.*; law expenses, £144 5*s.* 9*d.*; stationery, printing, &c., £405 10*s.* 7*d.*; salaries, wages, and pensions in the three departments—Museum, Library, and College—£4782 6*s.*; lectures, catalogues, specimens, &c., for museum, £346 11*s.* 11*d.*; purchase and binding of books, &c., for library, £740 4*s.* 2*d.*; trust funds, £339 2*s.* 2*d.*; purchase of stock, £2505 14*s.*; fees returned to candidates, £427 7*s.*; corporation duty, paid under protest, £158 1*s.*; Metropolitan Asylums Board (re-payable), £295 17*s.* 10*d.*; miscellaneous items—i.e., printing calendar, fuel and light, furniture, &c.—£727 16*s.*; disbursement of Goldsmiths' Research Grant, £176 5*s.* 7*d.* The expenses of the Museum and Library are exclusive of rates, taxes, repairs, fuel, light, &c.

The Secretary's report contains an abstract of the work done by the Council and committees, the Committee of Management of the two Royal Colleges, the Research Laboratories on Victoria-embankment, also reports of meetings of Fellows and Members, elections, &c. From the annual report of the Finance Committee we find that the gross income of the College for the past collegiate year is £804 less than the gross income of the previous year. This decrease is due to the falling-off in the receipts from the examinations of the Combined Examining Board. Under this head there is a decrease of £530 on the First Examination, of £240 on the Second, and of £842 on the Final, while there is an increase of £249 on the Diploma Fees paid by University candidates, making altogether a net decrease on these examinations of £1363. The receipts from the Fellowship and Dental Examinations continue at a satisfactory figure, being in each case higher than in any previous year.

The expenditure of the College for the past year is £1341 less than the expenditure of the previous year. This large difference is chiefly due to a reduction of £957,—arising in consequence of the smaller number of candidates examined, in the amount of the fees paid to the examiners under the combined Examining Board. This reduction, of course, to a great extent compensates for the decrease of £1363 in the receipts. The expenses, however, which are less liable to variation than the examiners' fees, have in most instances been smaller than in the previous years. There is thus a reduction of £248 in the expenses of the Examination Hall, of £140 in the expenses of the laboratories, of £445 in the general working expenses of the College in Lincoln's Inn Fields, and of £239 in the special expenses of the Museum. The expenses of the Museum have not been so low for several years, but the difference in the general working expenses of the College is only brought about by the inclusion under this head in the previous year of a payment of £405 for seven years' insurance. There is only a difference of about £4 in the special expenses of the Library for the two years (the difference being in favour of last year), this being the department of expenditure least liable to variation. The extraordinary expenditure has been even heavier than in the preceding year, the chief item being a sum of £753 expended on reconstructing and redecorating the Lecture Theatre. The balance on the "income and expenditure" account amounts to £2015. The fact that so large a margin has been left, notwithstanding the heavy expenditure on the Lecture Theatre, must be regarded as very satisfactory and as an indication of the sound financial position of the College.

From the report of Dr. G. Sims Woodhead, the Director of the Research Laboratories of the two Royal Colleges, it appears that on June 4th last the number of those working or having received permission to work in the laboratories was 14. The agreement with the Metropolitan Asylums Board for the examination in the laboratories of specimens from the throats of the diphtheria patients admitted to the hospitals of the Board was continued up to Dec. 31st, 1896. During the half year, from June 5th to Dec. 31st, 8701 specimens, or an average of 55·4 per diem, were examined and reported upon. The Board have now made arrangements for the conduct of this work in their own hospitals.

The preparation of antitoxic serum for the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board has been carried out during the year, and this work is to be continued for the Board. From June 5th, 1896, to June 4th, 1897. the Director has supplied 8473 doses of 4000 units, 1539 of 3000 units, 350 of 2000 units, 786 of 1500 units, and 3258 doses of 1000 units (or no less than 43,646 doses of 1000 units each).

The grant entrusted to the two Royal Colleges by the Goldsmiths' Company is still being administered by the Laboratories Committee for the furtherance of the antitoxin treatment of diphtheria. Since the last annual report on the work done in connexion with the grant, Dr. Cartwright Wood has continued his investigations on the production of potent diphtheria antitoxins and has succeeded by his new method in obtaining large quantities of strong antitoxic serum. The strongest of these serums prepared by Dr. Wood has been supplied to Dr. Sidney Martin at University College Hospital, who reported to THE LANCET, Oct. 17th, 1896, that he had obtained most remarkable results by its use. In 1894 the percentage death-rate from diphtheria in that hospital was 39. In 1895, the first year in which antitoxin was used, the death-rate had fallen to 28, and in 1896 (Sept. 22nd), when the strong serum was used, to 20·5. In Dr. Martin's figures additional evidence is supplied of the importance of the treatment of diphtheria by antitoxic serum at as early a stage of the disease as possible.

During the past collegiate year many valuable specimens have been added to the Museum of the College; these have already been noticed in THE LANCET of July 24th, p. 209.

In the Library Department Mr. Victor Gustave Plarr, B.A. Oxon., formerly librarian to King's College, London, has been

Digitized by Google

appointed to succeed the late Mr. James Blake Bailey, B.A. Oxon., who died, regretted by all who knew him, on April 14th, 1897. Mr. Bailey was appointed librarian in 1887. On the completion of the additions to the library premises in 1888 the collection of books was re-arranged by Mr. Bailey, and under his able management many improvements have since been introduced whereby the value of the library as a place of study and reference has been very greatly increased.

THE FRONTIER RISINGS.

THERE is not much to be chronicled this week in the way of news regarding the tribal fighting on the Indian frontier, the bulk of which has probably yet to come. There is an apparent lull at the present time, but it is only apparent, for the preparations for the advance of Sir William Lockhart's large force to Tirah have been proceeding most actively, and the expedition is now ready; 30,000 men, at the least, have been mobilised and active operations will begin at once. Meanwhile, the tribesmen in the Khyber have attacked our troops at Fort Jumrud, and the Orakzais and Afridis are understood to be assembling in force. Winter is apparently setting in, for there has been a heavy snowfall in the Safed Koh range of mountains. The Mamund tribe have surrendered and are giving up their arms and the tribes have been offered medical aid for their wounded by General Blood. Notwithstanding all the disastrous events that have recently taken place in India, and the anxiety and hard work to which these have given rise, the conduct of affairs in that country has apparently been very energetic and judicious under exceptionally trying circumstances. The Government has lost no time in dealing with this big frontier outbreak. It was not an occasion, as we have said, for arguing, but for action; the rebellion must be put down by force and the tribes that have taken part in it subdued and disarmed. It is a very fortunate circumstance that the present Viceroy was appointed by the late Government and not by the present Ministry.

All that Lord Elgin has done since his appointment has been based, of course, upon the knowledge he has acquired in the country as Viceroy of India and as one responsible for the government of that great Eastern dependency. We see that Lord Onslow, in his courageous and statesmanlike speech at Guildford the other day, altogether denies that there has been any breach of faith with the tribesmen of the Chitral districts, maintaining, on the contrary, that the proclamation had been adhered to and fulfilled. What Lord Elgin had done had been done deliberately in what he conceived to be a spirit of justice to the tribes and in the interest of the country over which he ruled. The last persons to attack his policy would seem to be the party who appointed him to the post he now fills, and in any case Lord Onslow is justified in saying that there was no alternative between trusting and removing a high official charged with grave responsibility under most difficult circumstances. That the present Viceroy enjoys the confidence of those in India is undoubted, and nothing is more gratifying than the way in which the Rajahs have come forward to join the soldiers of the Queen, or the bravery, devotion, and loyalty exhibited by the native troops. The sick and wounded, we are glad to say, are reported to be doing well. The Royal West Kent Regiment has been escorting a large convoy of sick to Panjkora. The latest papers from India are, as might be expected, full of details respecting the military operations on the frontier, but their news is discounted by the fact that it has for the most part already arrived here by telegraph. From intelligence which has reached us we gather that the hospital service has worked satisfactorily and well. Great stress is laid upon the extremely difficult nature of the country, upon the fatigue and hardship imposed upon the troops by their expeditionary marches, the heat of the climate and great diurnal changes of temperature, and the difficulties in regard to food-supply, but the health and spirits of the troops—British and native—are, all things considered, very good.

The base hospital of the Malakand Field Force is, or was, at Nowshera. From a communication we have received we learn that the hospital patients, many of whom are officers, consist of wounded from Malakand Fort and district and cases of dysentery and fever, and among the latter several of enteric fever. It had been very hot, but the evenings were (the end of September) getting cool; there were occasional dust-storms. An officer of the Guides who had been seriously ill was getting quite well, and the patients generally were progressing favourably. The medical and nursing staff of the hospital had, of course, been very busy and all engaged had had an active time of it.

THE BATTLE OF THE CLUBS.[1]

THE POSITION AT YARMOUTH: A LIBERAL JOURNAL.

"IT should be remembered that above and beyond professional interests are the public, and surely those who are the paymasters of the profession have the right to dictate the terms upon which they shall be served." So says the *Eastern Daily Press* of Oct. 8th in referring to the relations which exist between the friendly societies and the medical men in the town of Yarmouth. What sentiments from a "Liberal" journal, as we believe the *Eastern Daily Press* to be! The *Eastern Daily Press* also says that the "doctors came into conflict with the societies upon a pocket question." This is not true. The facts are that the medical men and the clubs always worked amicably together with mutual benefit until the clubs from being benefit societies for *bonâ-fide* working men turned themselves into so-called medical aid societies, which only paid the medical officer a proportion of the sum earned by his labours, allowed him no voice in the selection of members, and admitted the well-to-do to their charity. The doctrine that the paymaster has a right to dictate terms to his employed may appear to be a sound one to this singular Liberal journal, but how would it work in practice? For instance, why should not the public demand their *Eastern Daily Press* for a farthing instead of a penny, or seek to have advertisements inserted at a half-penny per column or at some reduced rate? The public are the paymasters of the paper, why should they not "dictate the terms upon which they shall be served"? If this argument were alone employed by the masters in the engineering strike, would the *Eastern Daily Press* side with the masters? We will not labour the point, for it is clear that the *Eastern Daily Press* wrote with but little comprehension of medical matters or the actual position between general practitioners and medical aid associations.

A correspondent writing under the pseudonym of "Medicus" replied on the following day in excellent terms to the reflection of the Liberal newspaper upon the medical profession, and with laudable fairness the letter was inserted as a whole. A portion of it we quote: "The medical profession," he wrote, "naturally objects in its own interests to a system which deprives it of a large portion of its legitimate earnings, and hence considers the conduct of such of its members as consent to undergo this 'sweating' as 'infamous,' a term which has been employed by the Medical Council for unprofessional conduct. Your leader goes on to state 'that above and beyond professional interests are the public.' Just so. Those who are best able to judge are of opinion that the public cannot be properly attended to by medical men who undertake to 'physic them wholesale.' The proportion of two medical men to the 6000 members in Yarmouth and to 11,000 in Norwich speaks for itself. The whole system which governs these newly constituted medical institutes and medical aid societies is not only degrading to an honourable profession, but is equally detrimental to the best interests of that class of the public who have until recently been glad to avail themselves of the services of their club doctors."

This puts the whole matter in a nutshell and quite deprives the persons who take club appointments that have been refused by their fellow practitioners of the claim that is constantly put forward for them that they act out of humanity. They do nothing of the kind. It is not humane to bolster up a system of medical attendance which is not only based upon robbery of the medical profession, but which

[1] A reprint of the previous articles on the above subject has been published in book form entitled, "The Battle of the Clubs," and can be obtained from THE LANCET Office, price 1s.

Digitized by Google

offers at the same time totally inadequate care to the sick poor. It is not humane. It is on the other hand cruel as well as stupid.

THE HEARTS OF OAK SOCIETY AND THEIR MEDICAL OFFICERS.

The following circular has been received by one of the medical examiners to the Hearts of Oak Benefit Society:—

322, Winchester House, Old Broad-street,
London, E.C., Sept. 6th, 1897.

THE HEARTS OF OAK AND THE PRINCE OF WALES'S HOSPITAL FUND COMMEMORATION STAMPS AND STAMP ALBUM.

SIR,—I have the full permission of the Committee of the Hearts of Oak for placing the following facts before you and for asking you to assist in this matter as medical officer to the Society, and should further be glad to know if you will inform me whether your medical agent (if you have one) is trustworthy, and if he can be employed in the same benevolent object.

The Prince of Wales's Commemoration Hospital Fund Stamp was issued to afford those who could subscribe a small sum a tangible memento of this charity.

The Stamp is printed in two colours, blue price one shilling, and red price half-a-crown. The die having been destroyed in the presence of the Duke of York no more can be issued.

The stamp was not only issued to benefit the Hospitals, for the object which the Prince of Wales had also at heart was to interest the working classes in this noble and benevolent scheme.

An album in ornamental form is now to be issued containing pages for the stamps for several years, a letter from Lord Rothschild, reproductions of the portraits and signatures of Her Majesty the Queen and H.R.H. the Prince of Wales, as well as explanation how the production of it with the owner's own signature therein will ensure the bearer or his family immediate and special attention in any Hospital.

Thus the working man will benefit himself (subject, of course to the prior assistance of your own valuable organisation) whilst he assists the charity.

The Album will be sold to him at the price of 6*d.* net.

You, Sir, can obtain it at the trade price either from the Hearts of Oak office, 17, Charlotte-street, Fitzroy-square, or from me. This not for cash, but on sale or return at about one month.

The stamps also so obtainable carry a 10 per cent. commission on all sold direct from me or as arranged by you with the Hearts of Oak office, as they have the 10 per cent. on all sold through them.

A special notice of such sales will be communicated to the press, and further particulars will be found in the September issue of the *Hearts of Oak Review*.

May I hope you will kindly favour me with a reply and state what number of Albums I may be permitted to place with you.

Believe me, yours faithfully,
H. S. C. M. GORDON,
Acting for the Prince of Wales's Hospital Commemoration Fund.

It is characteristic of the position to which lay organisations attempt to degrade their medical men that they should ask them to tout for the sale of books among their patients, whether "on sale or return" or on any other principle. We should much like to know, too, why any "bearer or his family" should obtain "immediate and special attention in any hospital" because he had bought a sixpenny album. We do not see why the hospital authorities should not resent the attempt to interfere with their routine and even refuse to see the patient who put forward greedy claims to earlier and more particular treatment than other sick poor. We should much like to know who Mr. H. S. C. M. Gordon is, and what right he has to describe himself as acting for the Prince of Wales's Commemoration Fund. The authorities of the Fund are privy to this circular, we suppose? If they are we are sure they have not realised what it means. If they are not, Mr. H. S. C. M. Gordon should be made to explain by what right he signs as acting for the Fund.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6349 births and 3414 deaths were registered during the week ending Oct. 9th. The annual rate of mortality in these towns, which had declined in the eight preceding weeks from 29·5 to 16·8 per 1000, further fell last week to 16·2. In London the rate was 15·5 per 1000, while it averaged 16·7 in the thirty-two provincial towns. The lowest rates in these towns were 9·4 in Portsmouth, 9·9 in Croydon, 10·9 in Halifax, and 11·5 in Blackburn; the highest rates were 21·3 in Sunderland, 21·7 in Manchester, 25·1 in Wolverhampton, and 26·2 in Bolton. The 3414 deaths included 433 which were referred to the principal zymotic diseases, against 608 and 514 in the two preceding weeks; of these, 131 resulted from diarrhœa, 86 from diphtheria, 73 from "fever" (principally enteric), 52 from measles, 47 from whooping-cough, and 44 from scarlet fever. No death from any of these diseases was recorded last week in Croydon; in the other towns they caused the lowest death-rates in Bristol, Brighton, Nottingham, and Blackburn; and the highest rates in Newcastle-upon-Tyne, Sunderland, Preston, and Wolverhampton. The greatest mortality from measles occurred in Burnley and in Sunderland; from scarlet fever in Huddersfield; from whooping-cough in Plymouth and in Gateshead; from "fever" in Wolverhampton; and from diarrhœa in Wolverhampton, Oldham, Preston, and Salford. The 86 deaths from diphtheria included 53 in London, 6 in Cardiff, 5 in West Ham, 3 in Leicester, and 3 in Liverpool. No fatal case of small-pox was registered during last week either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 3653, 3697, and 3677 at the end of the three preceding weeks, had risen again to 3692 on Saturday last, the 9th inst.; 400 new cases were admitted during the week, against 376, 358, and 349 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 165 and 167 in the two preceding weeks, further rose last week to 176, but were 47 below the corrected average. The causes of 28, or 0·8 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Leeds, Hull, Newcastle-upon-Tyne, and in sixteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Preston, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·8 and 19·4 per 1000 in the two preceding weeks, further rose to 19·8 during the week ending Oct. 9th, and exceeded by 3·6 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 8·5 in Perth and 15·9 in Leith to 22·0 in Greenock and 24·2 in Dundee. The 590 deaths in these towns included 28 which were referred to diarrhœa, 13 to scarlet fever, 12 to whooping-cough, 12 to "fever," 5 to diphtheria, and 3 to measles. In all, 73 deaths resulted from these principal zymotic diseases, against 78 in each of the two preceding weeks. These 73 deaths were equal to an annual rate of 2·4 per 1000, which slightly exceeded the mean rate last week from the same diseases in the thirty-three large English towns. The 28 fatal cases of diarrhœa showed a decline of 13 from the number in the preceding week, and included 15 in Glasgow, and 5 in Dundee. The deaths referred to scarlet fever, which had been 6 and 5 in the two preceding weeks, rose again last week to 13, of which 5 occurred in Glasgow, 3 in Edinburgh, and 3 in Aberdeen. The 12 fatal cases of whooping-cough showed a further decline from the numbers recorded in recent weeks, and included 7 in Glasgow and 3 in Dundee. The deaths referred to different forms of "fever," which had been 9 and 7 in the two preceding weeks, rose again to 12 last week, of which 7 occurred in Glasgow, 2 in Edinburgh, and 2 in Paisley. The 5 fatal cases of diphtheria included 2 in Glasgow and 2 in Dundee. The deaths from diseases of the respiratory organs in these towns, which had been 96 and 137 in the two preceding weeks, further rose to 162 last week, and were more than double the number recorded in the corresponding week of last year. The causes of 28, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·3 and 26·5 per 1000 in the two preceding weeks, further declined to 21·9 during the week ending Oct. 9th. During the thirteen weeks of last quarter the death-rate in the city averaged 24·0 per 1000, the rate during the same period being 19·4 in London and 18·4 in Edinburgh. The 147 deaths registered in Dublin during the week under notice showed a decline of 31 from the number in the preceding week, and included 17 which were referred to the principal zymotic diseases, against 39 and 20 in the two preceding weeks; of these, 10 resulted from diarrhœa, 4 from "fever," 3 from

scarlet fever, and not one either from small-pox, measles, diphtheria, or whooping-cough. These 17 deaths were equal to an annual rate of 2·5 per 1000, the zymotic death-rate during the same period being 2·0 in London and 1·8 in Edinburgh. The fatal cases of diarrhœa, which had been 21 and 8 in the two preceding weeks, rose again to 10 last week. The deaths referred to different forms of "fever," which had been 6, 9, and 6 in the three preceding weeks, further declined to 4 last week. The mortality from measles slightly exceeded that recorded in the preceding week. The 147 deaths in Dublin last week included 34 of infants under one year of age and 39 of persons aged upwards of sixty years; the deaths of both infants and of elderly persons showed a decline from those recorded in the preceding week. Eight inquest cases and 6 deaths from violence were registered; and 48, or nearly a third, of the deaths occurred in public institutions. The causes of 14, or nearly 10 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during September in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 13·3 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 8·7, 11·2, and 10·2 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Hammersmith, St. George Hanover-square, Marylebone, Hampstead, Stoke Newington, St. Martin-in-the-Fields, and Plumstead; while they showed the largest excess in Clerkenwell, St. Luke, Bethnal Green, Whitechapel, Mile End Old Town, St. George Southwark, and Battersea. Only one case of small-pox was notified in London during September, against 4, 7, and 1 in the three preceding months; this case belonged to St. Pancras sanitary area. No small-pox case was admitted into any of the Metropolitan Asylum Hospitals during September, and no patients remained under treatment at the end of the month. The prevalence of scarlet fever in London showed a marked increase upon that recorded in recent months; this disease was proportionally most prevalent in St. James Westminster, Hackney, Strand, St. Luke, Whitechapel, Limehouse, Mile End Old Town, Newington, Rotherhithe, and Battersea sanitary areas. The Metropolitan Asylum Hospitals contained 3585 scarlet fever patients at the end of September, against 2786, 3064, and 3390 at the end of the three preceding months; the weekly admissions averaged 350, against 272, 364, and 346 in the three preceding months. The prevalence of diphtheria in London showed an increase upon that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Fulham, Clerkenwell, St. Luke, Bethnal Green, Whitechapel, Bermondsey, Battersea, and Camberwell. There were 1033 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of September, against 864, 957, and 1006 at the end of the three preceding months; the weekly admissions averaged 150, against 125, 139, and 131 in the three preceding months. The prevalence of enteric fever in London during the month under notice showed a marked further increase upon that recorded in recent months; this disease was proportionately most prevalent in Stoke Newington, Hackney, St. Luke, City of London, Shoreditch, Limehouse, and St. Olave Southwark sanitary areas. The Metropolitan Asylum Hospitals contained 173 enteric fever patients at the end of September, against 70, 82, and 133 at the end of the three preceding months; the weekly admissions averaged 28, against 20 and 26 in the two preceding months. Erysipelas showed the highest proportional prevalence in Marylebone, St. Giles, St. Luke, Bethnal Green, Whitechapel, and St. George Southwark sanitary areas. The 23 cases of puerperal fever notified in London during September included 3 in Islington and 2 each in Kensington, Marylebone, Wandsworth, Camberwell, and Greenwich sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the five weeks ending Saturday, October 2nd, the deaths of 6687 persons belonging to London were registered, equal to an annual rate of 15·6 per 1000, against 13·9, 18·3, and 23·7 in the three preceding months. The lowest death-rates during September in the various sanitary areas were 10·7 in Hampstead, 11·2 in Wandsworth, 11·5 in St. James Westminster, 11·6 in Stoke Newington, 11·9 in St. George Hanover-square and in Lewisham (excluding Penge), 12·5 in Kensington, and 12·8 in Lee; the highest rates were 20·4 in St. George Southwark, 21·0 in St. Luke, 21·4 in Bermondsey, 21·5 in Shoreditch, 21·7 in Limehouse, 22·4 in Clerkenwell, and 25·5 in St. George-in-the-East. During the five weeks of September 1050 deaths were referred to the principal zymotic diseases in London; of these, 485 resulted from diarrhœa, 187 from diphtheria, 126 from whooping-cough, 93 from measles, 85 from scarlet fever, 73 from enteric fever, and 1 from an ill-defined form of continued fever. These 1050 deaths were equal to an annual rate of 2·5 per 1000. No deaths from any of these diseases were registered last month in St. Martin-in-the-Fields; in the other sanitary areas they caused the lowest death-rates in St. George Hanover-square, Hampstead, Stoke Newington, St. Giles, Holborn, and Lee; and the highest rates in Clerkenwell, Shoreditch, St. George-in-the-East, St. George Southwark, St. Olave Southwark, Bermondsey, and Plumstead. The 93 fatal cases of measles were 16 below the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Shoreditch, Whitechapel, Limehouse, and St. George Southwark sanitary areas. The 85 deaths referred to scarlet fever were 36 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Clerkenwell, St. George-in-the-East, Bermondsey, and Rotherhithe. The 187 fatal cases of diphtheria were 16 below the corrected average number; the mortality from this disease was highest in Clerkenwell, Whitechapel, St. George Southwark, Bermondsey, Battersea, and Wandsworth sanitary areas. The 126 deaths from whooping-cough were 28 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, Chelsea, Shoreditch, Bethnal-green, and St. George Southwark. The 73 fatal cases of enteric fever were within 2 of the corrected average number; this disease was proportionally most fatal in St. George Southwark sanitary area. The 485 deaths from diarrhœa were very slightly below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in St. Luke, Shoreditch, St. George-in-the-East, St. Saviour Southwark, and St. George Southwark. In conclusion, it may be stated that the mortality during September from these principal zymotic diseases was nearly 9 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths of children under one year of age to registered births, was equal to 156 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Stoke Newington, St. Giles, Holborn, St. Olave Southwark, Lewisham, and Woolwich; and the highest rates in St. Martin-in-the-Fields, Clerkenwell, Shoreditch, St. George-in-the-East, Limehouse, Bermondsey, and Lee.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT P. MACKESSACK, A.M.S., having reported himself at the Royal Victoria Hospital, Netley, for duty, is posted to the Surgical Division from Oct. 5th. Brigade-Surgeon-Lieutenant-Colonel Frederick Lyons, M.D., retires on retired pay.

1st Life Guards: Surgeon-Major Horatio R. O. Cross, from Royal Horse Guards, to be Surgeon-Major, vice Surgeon-Lieutenant-Colonel J. S. Forrester, F.R.C.S. Edin., who exchanges.

Royal Horse Guards: Surgeon-Lieutenant-Colonel James S. Forrester, F.R.C.S. Edin., from 1st Life Guards, to be

Digitized by Google

Surgeon-Lieutenant-Colonel, vice Surgeon-Major H. R. O. Cross, who exchanges.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of the under-mentioned officers are placed permanently at the disposal of the Government of Bengal:—Surgeon-Captain Sunder (Bengal), Surgeon-Captain Maynard (Bengal), Surgeon-Captain O'Kinealy, and Surgeon-Captain F. C. Clarkson. The services of Surgeon-Lieutenant King (Bombay) are replaced at the disposal of the Military Department. Surgeon-Captain McNaught, A.M.S., has been transferred from the Bombay District to the Quetta District. Surgeon-Captain Newland, A.M.S., has been transferred from the Quetta District to the Nagpore District. Surgeon-Captain Hodgens, A.M.S., has been transferred from the Nagpore District to the Bombay District.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major R. M. P. Low, M.B., resigns his commission. The under-mentioned officers to be Surgeon-Majors:—Surgeon-Captain F. W. Gibbon, Surgeon-Captain A. B. Wade, M.B., and Surgeon-Major Walter Smith Cheyne, M.B., 2nd Volunteer Battalion the Gordon Highlanders.

VOLUNTEER CORPS.

Rifle: 4th (Cambridge University) Volunteer Battalion the Suffolk Regiment: Surgeon-Lieutenant L. E. Shore, M.D., to be Surgeon-Captain.

INDIAN AFFAIRS.

In addition to the news regarding the Tirah expedition now starting, the return of the forces with their sick and wounded from the Mohmand expedition, and the progress of the plague in the Bombay Presidency, we learn that there has been a daring and unexpected Burmese raid on Mandalay Fort. Things have generally been very quiet in Mandalay since its occupation by the British, although there has been from time to time a good deal of disturbance on the part of dacoits in Upper Burmah beyond it. The attack on Mandalay Fort was happily a very small affair. On the part of the garrison, an officer and two sepoys of the Madras Infantry were wounded, and a private of the Royal Scots seriously so. Troubles, like other things, rarely come singly. The Indian Government has its hands full of responsible work at the present time, and the drain—actual and potential—on its exchequer must be very great.

THE NILE EXPEDITION.

We have heard but little of late of General Kitchener's expeditionary force. Meanwhile, a work is being pushed on which will have an excellent effect on the future material interests of the country and on its pacification—namely, the railway. This is to be extended to Berber, and the Egyptian Government has granted the money for the purpose. Kassala is to be occupied by Egyptian troops in December. It seems probable that an advance will take place towards Khartoum early in next year.

The *Broad Arrow* says: "A large brass tablet mounted in oak is shortly to be placed in Haslar Chapel in memory of the two naval surgeons who lost their lives in the Benin Expedition. The memorial has been subscribed for by the medical officers of the Royal Naval Hospital and the brother officers of the deceased surgeons who went through the instructional course together at Haslar. Round the tablet is a cable-pattern border, and in each corner a naval emblem or crest. The inscription runs as follows: 'In memory of Surgeon Charles T. Fife, R.N., aged thirty, who was killed in action February, 18th, 1897, while attending to a wounded comrade; and Surgeon Richard H. Way, R.N., aged twenty-nine, who died of heatstroke February 21st, 1897, during the Benin Expedition. Erected by Naval Medical Officers.'"

We regret to learn that Surgeon-Major Semple, Assistant Professor of Pathology in the Army Medical School, who, it will be remembered proceeded to Maidstone to vaccinate against typhoid fever, has been obliged to return to Netley owing to an attack of Malta fever. Surgeon-Captain W. B. Leishman, M.B., has, we hear, arrived at Maidstone to continue the work which Surgeon-Major Semple initiated.

We understand that there are three commissions vacant in the Militia Medical Staff Corps. Under recent regulations an officer joining can have five or six months' employment during the first year. Early application should be made to the Officer Commanding Militia Medical Staff Corps, Aldershot.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on the 12th inst., Inspector-General W. H. Lloyd, M.D., being in the chair, the sum of £48 was distributed among the several applicants.

"Audi alteram partem."

"THE EPIDEMIC OF TYPHOID FEVER AT MAIDSTONE."

To the Editors of THE LANCET.

SIRS,—I have read with interest the report of your Special Sanitary Commissioner on the epidemic of typhoid fever in Maidstone, but cannot agree with all his conclusions. I will admit that the drainage system is perfect only in theory. Some of the main trunks have been badly laid, and many of the terminals are not properly flushed. But the condition in September, 1897, is much better than it was a year or two ago, and the figures your Commissioner quotes "show laudable activity on the part of the sanitary authorities." Now, typhoid fever has never been epidemic in Maidstone before, so that the sewers when in a worse condition than at present never produced typhoid fever.

Your Commissioner seems astonished at the "extraordinary susceptibility of the inhabitants of the three infected and high districts," and he describes "the immunity which the inhabitants of the low-lying central districts have enjoyed" as "equally extraordinary." Surely the reason is perfectly simple; the three high districts are supplied with the same poisoned water from the reservoir at Barming (Farleigh water) which can alone supply them, whereas the central district is supplied direct from the chalk at Boarley or from the springs at Cossington. Moreover, the western district—i.e., that nearest the Barming reservoir—has suffered more severely than either the north-eastern or the south-eastern areas of distribution of the Farleigh water. I may add, too, that some of the most severe cases (described by Sir William Broadbent as "virulent") occurred in one family at Barming who derived their water direct from the rising main as it ascends from the Farleigh pumping station to the Barming reservoir. The household consisted of seventeen persons; seven members of the family, all water-drinkers, suffered from the fever, two have died and two more are barely recovering from a virulent attack. All the servants escaped; they never drank water except when boiled as tea, &c., always drinking beer (brewed in Maidstone) for their dinner and supper.

I will relate the experience of my own terrace. There are six houses draining into a common drain which crosses a lawn and empties into the common sewer with an interceptor. No. 1, eight persons, drink water from their own well; no cases. No. 2, ten persons, drink water from their own well; no cases. (In both the above the company's water is not laid on.) No. 3, eleven persons, drank water from their own well until Aug. 20th, when the water was thought to taste of carbolic acid and so the company's water was drunk; six cases, two severe. No. 4, ten persons, drink the company's water; four cases. No. 5, empty house. No. 6, seven persons drink the company's water; three cases, all very severe indeed. The incidence of the fever has been on the servants and children, all water-drinkers. I have no doubt that the water was the sole cause of all these cases.

Then, again, your Commissioner thinks 35 cases occurring in the central district as proving too much. People do not visit their friends to drink water, but tea or beer or wine, though many of the 35 cases have been proved to have partaken of the polluted water. I do not for one moment wish to minimise the importance of putting our drainage in order. In fact, at a meeting of the medical practitioners of the town called by the mayor on Oct. 7th a resolution was passed asking the sanitary authorities to flush all the house drains throughout the town as well as to ensure that in future they shall be all supplied with a good flush of water. One fact has not been mentioned in your report. In the middle of the month of August there were a great many cases of severe diarrhœa, some of which passed on to enteritis

Digitized by Google

and a few were fatal. The diarrhœa was associated with a temperature of about 103° F. on the first day and thus differed from the ordinary summer diarrhœa. I am informed that several such cases occurred among the inmates of Barming Asylum, which received its water-supply entirely from the Farleigh source. Four of these cases died from colitis as verified by post-mortem examination. Were not these people suffering the direct effects of the initial poison which they purged away, thus rendering them less likely to develop the specific form of typhoid fever?

I am, Sirs, your obedient servant,

Maidstone, Oct. 10th, 1897. CHARLES E. HOAR, M.D. Lond.

RESPONSIBILITY FOR THE INSANITARY CONDITION OF HOUSES.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 2nd, p. 871, you refer to a decision by the Recorder of Belfast that if a citizen takes an unfurnished house which is not in a sanitary condition "he must examine it" and "must at his own expense make it right. Neither the landlord nor the agent was bound to do so." May I venture to observe that this decision apparently requires qualification having regard to the Housing of the Working Classes Act, 1890, Sec. 75, which reads as follows: "In any contract made after the fourteenth day of August, one thousand eight hundred and eighty-five, for letting for habitation by persons of the working classes a house or part of a house *there shall be implied a condition that the house is at the commencement of the holding in all respects reasonably fit for human habitation.* In this section the expression 'letting for habitation by persons of the working classes' means the letting for habitation of a house or part of a house at a rent not exceeding in England the sum named as the limit for the composition of rates by Section 3 of the Poor Rate Assessment and Collection Act, 1869, and in Scotland or Ireland four pounds."

The annual rent limit referred to in the Poor Rate, &c., Act, 1869, is £20 (or 7*s.* 8*d.* per week) in London; £13 (or 5*s.* per week) in Liverpool; £10 (or 3*s.* 10*d.* per week) in Manchester and Birmingham; and £8 (say, 3*s.* 1*d.* per week) elsewhere.—I am, Sirs, yours faithfully,

CHARLES PORTER, M.D. Irel., D.P.H. Camb.,
Medical Officer of Health.

Health Office, Stockport, Oct. 12th, 1897.

THE IMMEDIATE REDUCTION OF ANGULAR CURVATURE OF THE SPINE.

To the Editors of THE LANCET.

SIRS,—A paragraph in THE LANCET of Oct. 9th, p. 931, reads to the effect that the above-named operation was performed for the first time in London on Sept. 15th of this year. May I venture to point out that this is incorrect? On Aug. 19th, at the North-West London Hospital, I reduced under anæsthesia an angular curve in the upper dorsal region of a girl aged two and a half years. The deformity readily gave way (with a slight crack) to moderate pressure, and the spine was easily maintained in an over-corrected position whilst a plaster case, which the patient still wears, was being applied from the head to the pelvis. Since the operation the general health of the patient has greatly improved.

I feel sure that Mr. Tubby would not regard an operation as "successful" until there had been time for the ultimate result of the operation to have been reached, and in this particular measure this cannot be known before many months have elapsed. Since this mode of treatment is still on its trial it is important that it should be used only in really suitable cases. Rapidly progressive cases with abscess formation or fever on the one hand and on the other old healed and ankylosed cases are in my opinion unsuitable, and if they are treated by this method discredit is likely to be thrown upon what promises to be a very valuable help in the treatment of tuberculous kyphosis.

I am, Sirs, yours faithfully,

J. JACKSON CLARKE.

Old Cavendish-street, W., Oct. 9th, 1897.

"MEDICAL EVIDENCE AT CORONERS' INQUESTS."

To the Editors of THE LANCET.

SIRS,—I have read the annotation on the above subject in THE LANCET of Oct. 9th, and there are one or two points of general interest which arise out of it from a medical jurisprudence point of view. In the case of a man found dead it is quite common for the police or friends to call the medical man who lives nearest the spot. The medical man so called may be quite the most suitable person to speak as to the cause of death and as to the numerous other medico-legal points that may arise; but, on the other hand, he may not. He may be a man who, however good at his profession, knows nothing as to the nature of evidence; he may be incapable of distinguishing properly between the facts that he observes and the inferences that he draws from these facts. He may, too, from want of experience in the witness-box, not be able to answer questions in such a way as to make his meaning clear.

The medical man first called to the deceased may then not be the right man in the right place; it is a matter of chance whether he is or not. Now from your remarks it would seem to be implied that the theories of the first medical man were to be accepted without question, and that a second medical man who disagrees with those theories should not have given evidence. In the case in question you say the second medical man who was called was not present at the post-mortem examination. But what of that? He was called, not to controvert any facts observed by the other medical man—these he accepted—but to speak as to the deductions that he drew from those facts. He was there as an expert witness—a neither unusual nor unprofessional position for a medical man. The coroner in this case, when perfectly relevant questions were being put to the first medical witness by the solicitor who represented the friends of the deceased, said: "I will not allow cross-examination in the court" That surely would be a strange court of inquiry when witnesses could give their evidence without challenge and without cross-examination. It is to be noticed, however, that although the coroner in this inquest protected the medical witness from uncomfortable questions, yet he allowed the superintendent of police to cross-examine other witnesses. You say the thanks of the medical profession are due to the coroner for the way he conducted this inquiry. Why? Does the medical profession as a body put itself so incompetent in the witness-box that it wants to be saved from being cross-examined by a layman upon matters which the profession is supposed to be specially competent to deal with? If so, it does not say much for the confidence of the profession in their own capacity. If this is to be the rule it would follow that the most junior member of the profession just qualified might give in his evidence the most startling theories and he is not to be cross-examined as to them—that is to say, the accuracy and value of his evidence is not to be tested. How does it make for truth that in a court of justice the first statement of an expert witness is to be accepted without undergoing the best test of all evidence—viz., cross-examination?

I think the medical profession as a body have too much self-respect and too much desire for the truth to wish to escape from those tests to which all witnesses in every other profession are subject when they give evidence in court. If any expert medical witness gives evidence in the Queen's Bench he is liable to cross-examination. Why, then, in a coroner's court should this be considered improper, and why should the medical profession thank the coroner?

I am, Sirs, yours faithfully,

Bath, Oct. 12th, 1897. PRESTON KING, M.D. Cantab.

To the Editors of THE LANCET.

SIRS,—I have read your remarks in this case and feel sure you cannot have been made fully acquainted with the facts of the case. I send you the papers containing the reports of the inquest. You say that without my having seen the post-mortem examination I gave my evidence on generalities. I did not attend the post-mortem examination, but I fully and entirely accepted Dr. Heathcote's report as to this, and my evidence was based upon that and upon the other proved

Digitized by Google

facts in the case of which I had an equal opportunity with him of judging. My evidence was therefore not as to generalities, but based upon the actual facts of the case as proved by Dr. Heathcote and the witnesses who were present at the death. Wherein I differed from Dr. Heathcote was on the scientific conclusions to be deduced from those facts not in dispute.

Here was a man found in the road bruised and dying; he was fully conscious and stated twice that some one had knocked him down; his money was found on the pavement, his pocket was outside his trouser flap, and his keys were absent; asked where his keys were, he stated that they were in the road, some little distance away; this was found to be correct—they were found there. He had been seen by many people that day and was known to be in possession of money, and it was sworn that he had a £5 note in addition, but this was gone. Under these circumstances it was suggested that death was due to simple cardiac failure, and that the statement that he had been knocked down was a delusion due to the cardiac failure, although the statement he made in the same breath as to his keys was found to be absolutely true. It was also said by Dr. Heathcote that "the wounds on the back of the head were certainly caused by falling and that on the elbow also"; and that the marks on the face were "probably due to his struggling on to the footpath; you see he fell once, and I could distinctly see where he fell and then hit himself against the wall." All this as to his falling is pure surmise and Dr. Heathcote no more saw it than I did. Then being asked, Does not a man die suddenly as a rule in such a case; does he not fall down dead at once? Dr. Heathcote said: "Lying on the ground might make him recover somewhat, because dying on the ground there is less for the heart to do, and then when he attempted to get up he would faint again." He added that "people in that state very often say things that are not true; taking into consideration the general state, I should say he was under a wrong impression and was not hit."

Now I ask you, Sirs, if a man dying as suggested from sudden cardiac failure makes statements which are delusions, whilst he is able at the same time to state facts accurately? I simply say that it is not my experience; it does not appear to me to consist with the facts, and I have never met either in books or in the experience of my friends such a case. If the theory under such circumstances of sudden death from heart disease is so easily accepted, how simple and easy murder of a man with known heart disease will become. If the case was so simple as appears to be assumed, why did the coroner adjourn it three times and hold four distinct sittings, taking evidence at each, and why was such an effort made to trace the £5 note and a reward offered for its recovery? All this was surely beside the mark if it was a death from natural causes. The coroner himself remarked that if the deceased received a blow and failure of the heart resulted it was a case of murder. Dr. Heathcote said there was nothing to show that deceased had not received a blow.

Now the whole question resolves itself into this: Did the deceased die from primary heart failure or did he die from heart failure as the result of violence, he himself stating twice that he had been knocked down? Which is the more probable in these circumstances, that the deceased died from simple heart failure or from heart failure as a result of injury? To accept the former theory we have to assume that the deceased fell down from heart failure, fainted, got up again, walked a short distance, then fell down again in a second faint, and, after all this, was able to say to two persons that he had been knocked down, and also able to state correctly where his keys would be found, and that then he died from primary heart failure. In the theory that failure of the heart resulted from injury there is not a single difficulty and not one fact in the case which is not consistent with the deceased's own statement that he had been knocked down. It is to be remarked that the jury did not return a verdict of death from natural causes, as they would have done if the inquest had been closed at the first sitting, but that in consequence of the evidence subsequently given they left it in doubt by their verdict whether the deceased's death was due to violence or not.

I am, Sirs, yours faithfully,

WILLIAM H. COOKE,
Resident Medical Officer Royal United Hospital, Bath; late House Physician St. George's Hospital, London.

Oct. 12th, 1897.

THE PREHENSILE POWER OF THE HANDS OF THE HUMAN INFANT.

To the Editors of THE LANCET.

SIRS,—Will you allow me space in which to draw attention to the above character, which was ingeniously brought forward five years ago by Dr. Louis Robinson, before it becomes accepted as an argument for the descent of man from the lower animals? It has enjoyed a singular immunity from criticism, as far as I can learn, which seems hardly deserved. The observations made by Dr. Louis Robinson put into scientific form the previous experiences of mothers, nurses, and others who had occasion to notice the habits of the human infant, and none need dispute their substantial correctness, though I must add my negative testimony, which extends over about the same number of human infants as Dr. Robinson examined. I can only say that as yet I have not found one infant which could support its own weight by a finger or other object placed in its palm. Frequently an infant has partially, but never entirely, supported its own weight. However, this is only a matter of detail. Those children which I examined were nearly all of the well-to-do classes, and it would be worth enquiring whether, on the theory in question, these were more or less "ancestral" than those which Dr. Louis Robinson examined. Broadly speaking, the facts of the latter may stand undisputed. But what of their significance? They were sufficiently convincing for the late Professor Romanes, and perhaps ought to be so for us. He even thought fit to stereotype them in his able controversial work "Darwin and After Darwin." This prehensile power of the hand of the infant is certainly a reflex phenomenon, and is in excess of the muscular power of the infant in most other directions. Is it then an ancestral legacy from the "grapnel-like" grasp of the common ancestor of man and the higher apes—Pithecanthropus ignotus we may call it—still shown in the human infant as a "vestige" of a formerly useful power, or is it a mere physiological character, exactly what one would expect if man never had any other than human ancestors? I submit that the latter is the more reasonable view and propose the following simple explanation. During the last four or five months of fœtal life the familiar "movements" felt by the mother are very frequent, almost constant. These are undoubtedly of a reflex character, and if one may judge from those of the last two or three months are entirely caused by the lower limbs of the fœtus, except perhaps in those few cases in which the fœtus lies in an abnormal position, when the upper extremities may be more in motion than usual. During all these months the upper extremities must have had little or no muscular exercise through reflex influence, certainly not the flexor muscles, and the hands (fortunately for the maternal tissues) none at all. When the child is born one would expect nothing else than that the inherent power of grasp possessed by the hands, which is to be so conspicuously employed in later life in a purposive manner, should be disproportionately excited to reflex action by stimulation applied to the palm of the hand, and that the flexor muscles of the forearm and arm should react strongly to the influence of tension for the first time. At about the age of three weeks this disproportionate power of grasping begins to disappear and is gone, as such, in two or three months, when the novelty of reflex stimulation of the palm and flexor muscles has worn off. The explanation of this disappearance given by Dr. Louis Robinson is most lame—viz., that it is due to the rapid increase of fat and weight which takes place, and to failure to exercise the power. The latter has nothing to do with the point, for no practice of any kind served to maintain or originate the power. As to the second point, we know that an average infant, weighing seven pounds at birth, would weigh seven pounds, or less, after one week of life; after two weeks, perhaps seven and a quarter pounds; after three weeks seven and three-quarters, and so on, gaining weight at the rate of half a pound a week, or if an exceptional infant it might gain a pound a week. Thus, at the age of three weeks a seven-pound infant would have put on weight to the extent of three-quarters of a pound—a very "drop in the ocean" when compared with such striking muscular power as the human infant manifests in this particular performance. But this remarkable power of the infant in the matter of prehension does not stand alone among most powerful reflex actions which it is able to perform immediately it is

Digitized by Google

born. The post-natal cry of a baby in many cases is something startling for power and endurance. To take an extreme case, I remember one infant which, from the moment of its birth, for a solid three-quarters of an hour roared without five seconds' cessation, a feat which no strong man could perform. I remember it the more vividly by reason of the concurrent fact that the mother was all that time in a dangerous state from hæmorrhage. This was an exceptional feat, but purely a reflex phenomenon like that of Dr. Louis Robinson's infant which supported itself for "two minutes thirty-five seconds"! In most cases the power and endurance of this cry, shown for the first few days in most vigorous infants when their skin is exposed to the air for washing, is very striking, even if it disappear earlier than the prehensile power of the hand. The power of sucking possessed within five minutes of birth by a strong child, and the cry for food which so soon shows itself loud and strong, are only two more among many reflex phenomena which rank in significance or insignificance beside the particular character before us. There is also a phenomenon which the foot of the human infant manifests corresponding to that noticed in the hand by Dr. Louis Robinson which one is surprised that he did not proceed to investigate. I have examined the prehensile power of the toes of many infants ranging from a few hours to a year in age, and find it singularly constant. It is excited by placing a small finger or similar body in contact with the flexor surfaces of the toes, which immediately close upon the finger in an attempt at prehension. This muscular act is proportionately as strong and as quickly evoked in a child of a year old, when it is passing from the purely reflex to the purposive phase of life, as in a new-born infant. In later life, in the case of savages and others intelligent enough not to cramp their feet by tight boots, about the corresponding degree of prehensile power of the toes can be exercised voluntarily. One would like to know whether or not Dr. Louis Robinson would look upon this reflex action of the infant's foot as supporting the "vestige" theory. Is this also the vestige of a prehensile power which man's simian ancestors exercised in the course of their arboreal life? If it be so it behaves in a very different manner from the analogous phenomenon in the hand whose course is so brilliant and brief. The hand of man and the ape are not so strikingly different in structure or function, but the differences between the foot of man and that of the ape are profound as to structure not less than function, and these were strongly brought out by Sir William Turner in his address on Anthropology at Montreal this year. Sir William Turner there points out that the prehension of the foot of the ape is[1] more important than that of its hand, the pollex in apes being feebly developed. If man had any genetic connexion with the ape surely the "vestige" of prehension of his foot ought to be a more marked character than the corresponding "vestige" pertaining to his hand. It is not so, for, as pointed out, it is very feeble, it is persistent and varies little for a year or more, it corresponds closely to the degree of prehension which adults can exercise voluntarily, and it never is accompanied by an attempt on the part of the hallux at opposition, an act for which the anatomy of the foot in man is eminently unfitted. Moreover the difference between the response to reflex stimulation of the muscles of the upper and lower extremities in an infant is very striking, and to a degree which bears out the suggestion as to previous use or non-use during fœtal life which I have ventured to put forward. The slightest stimulation to the prehensile muscles of the hand and the flexor muscles of the arm and forearm, in attempted extension of the part, produces a prompt and strong resistance, as Dr. Louis Robinson has shown. It is not so with those of the lower limb, for in addition to the feeble prehension exercised by the toes, the muscles which flex the thigh upon the pelvis and those which flex the leg upon the thigh show a strange indifference to attempts at extension. The novelty of this class of action has worn off. The evidence which these phenomena are supposed to afford for the descent of man from the ape has indeed been overdone, and it resembles some of the other sensational lines of evidence of this class which are open to provokingly simple physiological and anatomical explanations, Darwinism apart. On this account I venture to think some expression of opinion upon this interesting subject is desirable.

I am, Sirs, yours truly,

Sept. 25th, 1897. WALTER KIDD.

[1] Reported in Nature, Sep 2nd, 1897, p. 430.

"THE COMPARATIVELY STATIONARY DEATH-RATE IN PRIVATE OBSTETRIC PRACTICE."

To the Editors of THE LANCET.

SIRS,—A perusal of "M.D.'s" letter on this subject in THE LANCET of Oct. 2nd suggests to one what an advantage it would be both to the public and the profession if a supply of good obstetric nurses asking from six to eight guineas a month were available. The certificated nurse usually requires ten guineas, her travelling expenses (since she generally resides in a large town), and her meals apart from the servants, often an insuperable objection to the lady engaging her. I have spoken to many of my medical friends on the subject and they agree with me that in the usual two and three guinea midwifery cases the trouble and anxiety that accrue principally from the ignorance and conceit of the nurses in charge make these cases not worth the fee earned, but of course a man must be very strong to be able to refuse them.—I am, Sirs, yours faithfully,

Oct. 9th, 1897. G. P.

IMPERFECT VACCINATION: A CASE THAT WANTS A REMEDY.

To the Editors of THE LANCET.

SIRS,—There is a matter which it seems should receive the attention of the General Medical Council; I refer to the most unfair working of the Vaccination Act. Public vaccinators in the instructions issued by the Local Government Board are strictly directed when vaccinating to make not less than four insertions, and, of course, their work is periodically inspected, while it is a notorious fact that there are men in the profession who do not hesitate to make three, two, or even one insertion only, according to the caprice of the parents, as I am constantly asked whether I will not vaccinate in "one or two places only as Dr. —— does," and on my refusal the child is taken elsewhere. Surely it is high time that anyone who is authorised to give a certificate of successful vaccination should be bound to conform to the Local Government order, and also if proved to be guilty of such unprofessional conduct should be censured by the General Medical Council, for not only is the public vaccinator mulcted of his fees for doing his duty, but the vaccination must be in many cases inefficient and hence calculated to bring it into greater disrepute.

I am, Sirs, yours faithfully,

Oct. 14th, 1897. A PUBLIC VACCINATOR.

THE EPIDEMIC OF TYPHOID FEVER AT MAIDSTONE.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

PERHAPS one of the most significant recent items of news from Maidstone is the announcement that two extra assistant sanitary inspectors have been appointed. Their special mission will be to make a house-to-house inspection of domestic drains. This sounds somewhat like closing the stable-door after the horse has been stolen; but, to judge by the continuation of the epidemic, it would seem as if there was more than one horse to be stolen. Also the same criticism may be made of every measure taken when once an epidemic has broken out. The importance of the appointment of extra sanitary inspectors rests in the double fact that it is a practical admission that there may be something else than the water-supply which has favoured the spread of typhoid fever; and, secondly, it shows that the general sanitary condition of the town is not as perfect as was at first inferred. Undoubtedly a great number of inhabitants of Maidstone were under the impression that the town was well drained and exceptionally healthy. Such a conviction cannot have been based on actual knowledge of the facts, but is more likely to have arisen from the favourable figures published as to the death-rate. The birth-rate was for 1896 equal to 23·91 per 1000, and the death-rate 13·47, and the medical officer of health in his last annual report adds that consequently "the total loss by

Digitized by Google

death in an equal number of persons, in all respects comparable as to age and sex, was 862 in Maidstone, as against 1000 in England and Wales at large, by which it is seen that we continue to hold the same enviable position for comparatively low death-rate." As against this it should be noted that the birth-rate is low and the zymotic death-rate is high. The average birth-rate at Maidstone for the decade 1870–79 was 32·50 per 1000 and for the decade 1880–89 it was 31·17, while last year it was only 23·91 per 1000. The zymotic death-rate was equal to 2·01 per 1000, the corresponding rate for England and Wales being 2·18. It is obvious that in a small country town like Maidstone the death-rate should be very low, for those special conditions which in great industrial centres favour a high death-rate should be absent. There was last year an excess of measles, 1·31, as compared with 0·56 for England and Wales, and of diphtheria, 0·44, as compared with 0·29 for England and Wales. The other zymotic diseases were considerably below the average for England and Wales. When we add to these figures, which are not altogether satisfactory so far as preventable diseases are concerned, the devastation made by the present epidemic there is evidence enough to justify the suspicion that the general sanitary condition is not all that could be desired. Under these circumstances we therefore welcome the announcement that two extra sanitary inspectors have been appointed.

Letters published in the local papers bear further witness to unsanitary conditions. Thus the *Kent Messenger* of Sept. 5th contained a letter from a local builder, Mr. J. H. Bridge, in which he advises everyone not to stand near the street sewer ventilators, which he qualifies as "a vile nuisance." He also observes that the sanitary authorities insist on a ventilating pipe from the house drains being carried up to the highest part of the buildings. But they also require an intercepting trap placed some five feet from the front door and connected with a fresh-air grating, "which every practical man knows full well is half the time discharging sewer-gas, while the fresh air is going down the higher pipe." Certainly if the sewers are cut off from the smaller ventilators they require a system of ventilation of their own, and under this head Mr. J. S. Anscomb, formerly mayor of Maidstone, writes in the *Kent Messenger* of Oct. 2nd that some years ago he recommended that all rain-water pipes "should have sealed joints the same as soil-pipes and communicate with the sewer. This, calculating two to each house, would open 10,000 ventilators, which, although small in diameter, would represent a capacity of 7000 superficial feet, and every ventilator, however small, in my opinion must be of importance." As there are now over 6000 houses in Maidstone the ventilation would be one-fifth more than the figures given by Mr. Anscomb. But if the sewers in the first instance had been properly laid and built, ventilation, though equally necessary, would not occasion the nuisance which is now the subject of many complaints. A self-cleansing sewer does not give off offensive odours.

A great deal has been said concerning the hop-pickers who came from the slums of London and are supposed to have contaminated one particular water intake—that of Tutsham-in-Fields. This source of supply is stated to have been cut off on Sept. 20th. If this had sufficed to put a stop to the epidemic there should now be no more or only very few fresh cases of fever. But if the yield from the Tutsham springs was cut off the mains were not disinfected, and there was some ground for supposing that perhaps some of the other sources of the Farleigh supply were also contaminated. The Special Sanitary Committee of the Maidstone District Council wrote on Sept. 25th to the water company asking them to cut off the entire water-supply known under the generic term of the Farleigh Supply. The Council held a special meeting on the 29th, and at that date this letter had not even been acknowledged. It was further announced that the directors of the water company were not going to meet before the ensuing Friday. What excuse was given for such delay has not yet transpired. On the Friday in question the directors of the water company decided to cut off the entire Farleigh supply, and this, it is believed, was done on the following day, Oct. 2nd, though, according to another account, the water was cut off on the 30th, the day previous to the meeting of directors. But again, on this as on the former occasion, the mains were not disinfected, so that the pure supply from Boarley and Cossington, where the water is derived from the chalk, passed through the pipes that had probably been rendered impure by the former presence of the Farleigh water. Dr. Theodore Thomson, the Local Government Board inspector, is stated to have urged that the pipes should be disinfected with lime previously to receiving a new and pure supply. This, however, was not done and the epidemic still continues. Well may the inhabitants of Maidstone clamour for a public inquiry into all these circumstances, for there is certainly urgent need of a full and ample explanation. Doubtless the Local Government Board is justified in replying to the request made for a public inquiry that "they do not consider that the holding of a public inquiry would in any way further the investigations of Dr. Thomson," but they have less reason to add "or assist in dealing with the outbreak." Even this last sentence, however, may be true so far as immediate measures are concerned; but it should not be forgotten that ultimately it is the electors who will have to deal with the matter, and how are they to know for what measures to vote if there is not a public inquiry?

The figures as to the number of notifications, it is urged, look more favourable if instead of the daily returns the weekly averages be taken. Thus for the first week, beginning Sept. 16th, there was a daily average of 67 cases, for the second week of 81 cases, for the third week of 59 cases, and for the following six days the average is only 23 cases—an average, however, that will be somewhat increased by the later returns. These figures seem to indicate that the epidemic is gradually subsiding; but if it is entirely due to the water-supply, and that water-supply has been suddenly cut off, should not the epidemic cease, if not with equal, at least with corresponding, suddenness? That this is not the case suggests that the mischief due to the water has not been entirely removed, that the pipes are still infected, or that there are other causes at work besides the water-supply. Food kept in houses and placed close to inefficiently trapped and flushed drains may be contaminated. Some little time ago it was discovered that a vendor of penny ices in Maidstone used to store his ice in his closet as a convenient place because he could easily drain the water from the melting ice into the pan of the closet. Now that there is so much typhoid fever in the town the closets are likely to be exceptionally dangerous. Let us remember also that hop-pickers did not confine their attention only to the hop-fields. It is computed that about 10,000 hop-pickers travelled through Maidstone last season; many of them lodged in Maidstone. There are seventeen public-houses that take in from four to fourteen men lodgers, and there is a large number of registered fourpenny common lodging-houses. One proprietor of these common lodging-houses let out 500 beds in the course of one month during the hopping season. Then there are many unregistered houses that take in hop-pickers. The tramps frequent the south-eastern district in numbers, and here there have been a great many cases of typhoid fever. The district council so far recognised this danger that they decided to build a municipal common lodging-house, but some seven months ago the matter was referred back till a site in a suitable position at a moderate price could be found. Nothing has been done since then. If, previously to the contamination of the water-supply, some portion of the drainage system had received typhoid dejections from these hop-pickers or from other persons, and if the drains are not properly cleaned and ventilated, mischief might be done and its effects might not be entirely removed the moment the water-supply is altered. If the sewers are not only deficient in respect to their ventilation and cleanliness, but also leak and contaminate the surrounding subsoil, then we have unhealthy and dangerous conditions which will only be modified with the advent of copious rains or with the rebuilding of those sewers that leak. All these are considerations which gain in importance as we find that the epidemic still lingers in spite of the alteration of the water-supply.

MEDICAL AND SCIENCE STUDENTS AND THE INDIA CIVIL SERVICE.

(FROM A CORRESPONDENT.)

THE advantages of the Indian Medical Service are sufficiently appreciated by students of medicine of the United Kingdom. It is probable, indeed, that many more would compete for these valuable appointments, were they fully aware of the stress and the hardship of competition in the

Digitized by Google

medical profession at home. Still, the number of candidates competing is adequate testimony to the knowledge of the advantages of the Indian Medical Service among the class from which competitors should be drawn; and there is no ground for extending to this service the criticism and charges which have for some time operated as a deterrent against properly qualified men offering themselves freely and numerously enough for corresponding posts in the army. But we are here concerned with a service even more dignified, responsible and pecuniarily attractive than the Indian Medical Service—I mean the India Civil Service itself. In directing the attention of "medical students" (as appears in the heading) to this service I am well aware that I am raising hopes where they have not been wont to be entertained, and, further, that I am even entering upon ground which is *terra incognita* to the bulk of the "medicals" and science men of our universities and colleges. Let it be understood, then, that I am dealing with facts and not mere conjecture. And, first, be it remembered that the India Civil Service is still the prince of public services open to competition. The initial salary is good—£300 to £400, according as the rupee is reckoned for England or for India. Opportunities for rapid promotion may not be as plentiful as they were under the old *régime* before the days of unrestricted competition, but they are regular and are deemed satisfactory. Entering the service when he is between twenty-one and twenty-three years of age, the successful candidate is at once launched on a career in which he is spared all anxiety in the matter of a competence both in active life and on retiring. When he is still under fifty he may leave the service with a pension of from £800 to £1000 per annum. Such is the epitome of the normal career—the lot of the man who has not been favoured of fortune, but has merely "gone through" the service and done his plain duty from day to day.

That this career, with prospects even in excess of those just sketched, is well within the reach of the "reading" men among our medical and science students it is the special object of this article to show. The character of the India Civil Service examination was changed by the authorities five years ago. The age-limits were raised from 17–19 to 21–23 years, and the subjects of examination and the marks assigned to each were greatly modified. It was the intention of the authorities that the university student might enter himself for the examination without breaking the line of study which he was following for a learned profession or for his own culture at college. Hence the very wide scope of the examination, and hence also the non-obligatory rule in respect of subjects: no subject is compulsory; a candidate may take up as many or as few as he pleases, and with the exception of English composition and mathematics the marks assigned to candidates in each branch are liable to deduction in order to secure that "a candidate be allowed no credit at all for taking up a subject in which he is a mere smatterer." The Oxford classic, accordingly, does not take up mathematics; the Cambridge wrangler shuns Greek and probably Latin; the History "First" tries to score something in classics and to be strong in his own special branch as well as in the cognate studies—political science and political economy, and perhaps English or Roman law. Under these conditions the medical and science student has an equal—an "even"—chance with the classical, the mathematical, or the history man, perhaps even a superior chance. A few facts and figures will make this clear. To Latin and Greek 750 marks each are assigned, and an exceptionally strong Oxford classic will make from 700 to 850 in the two combined. To mathematics (which only very fair mathematical students attempt) and to advanced mathematics 900 marks each are assigned, and a very strong Cambridge man may be considered safe for from 800 to 950 in the combined subjects, to judge by the marks obtained during the last four years. Both the classical and the mathematical man have a number of subsidiary or cognate subjects in which they naturally offer themselves for examination. Now, in addition to the three groups of students whose interests, as we have stated, are consulted in the competition—the classical, the mathematical, and the history man's—there is another. Seven subjects are grouped together in the syllabus of examination under the head of natural science. They are the following: elementary chemistry and physics, higher chemistry, higher physics, geology, botany, zoology, and animal physiology. To *each* of these 600 marks are assigned—subject, as usual, to a deduction in the case of the marks gained by each student, to ensure that the mere smatterer shall be discountenanced and discomfited. It is evident that, were a student free to offer all these sciences as given above he would be at a very material advantage compared with the non-science man. It is, therefore, provided (1) that not more than *three* of them can be taken up; and (2) that elementary chemistry and elementary physics (one subject) may not be taken up by those who offer either higher chemistry or higher physics or both. Even with this expedient and reasonable restriction, however, the science man has a fair field—perhaps, indeed, favour, if one may reckon from the marks obtained by those few who have taken up this branch in the examination.

Every year a number of our best reading medical students find themselves unsuited to the profession for which they are registered students. Some of them are drawn to science and the more or less uncertain prizes (in the worldly sense) which its pursuit promises to the fit; others are stranded. Not only, however, on those who withdraw from the professional study of medicine, but on all students of medicine of more than average merit I would impress the following definite facts and conclusions:—1. For the last three years every sixty appointments in the India Civil Service have been offered annually; this year (August—September) the number is sixty-six. Besides, there are now offered, as the result of the same examination, Eastern cadetships (for Ceylon, &c.) and "Class I." clerkships in the Home Civil Service, which, taken together, make about thirty appointments more. 2. The medical student at the close of his second *annus medicus* is very often just of age to compete—twenty-one years; and out of his prescribed professional course of study during his first two years he can offer three subjects conveniently, since he has four at his command—elementary chemistry and physics, botany, zoology, physiology. 3. The intending candidate will have to specialise on his three sciences. He will have to study the subjects carefully for himself and be guided by good men. But he may rest assured that the questions set are fair questions, and the practical examinations should especially commend themselves to the student who knows his work. 4. An excellent man may make 1100 to 1250 marks in his three sciences. Several have made 400 in a science subject already. Like the classical man and others the science man has other subjects on which to draw—say, English composition (as a certainty), for which 500 marks (without deduction for "smatterers") are allowed, French (500), German (500), and political science (400), which subject almost all take up. 5. In 1896 the last successful candidate for the India Civil Service made 1492 marks; fewer were required for an Eastern cadet appointment.

The writer will give an illustration from the case of a successful candidate last year, the particulars of which are well known to him. It is not a case of a medical student, for he believes that owing to ignorance of the conditions of the examination no medical student has yet competed. But on that very account the instance is the more striking. The candidate in question had no leanings towards science. He was a history man, strong in English history, but not sufficiently strong in the other history subjects and in cognate branches to warrant his dependence on these solely. In November, 1895—that is, ten months before the examination—he began geology and botany. During these ten months he had to keep up his work in English history, read widely in Roman and general modern history (most of it new ground), begin political science (apart from a general knowledge of the subject from history), and brush up Latin and French, which he had not touched for two years. Yet with all these drawbacks and without going through any university course in the two sciences mentioned the candidate in question scored an average of 200 in each of them—rather more in geology, rather less in botany. Had he specialised in science he might easily have doubled his marks in these two subjects.

Hitherto (since the coming into force of the revised regulations) the two most outstanding features of the India Civil Service examination have been the predominance of Oxford and Cambridge men in the successful list and the virtual absence of candidates offering natural science. It is the main purpose of this article to remedy this defect by calling upon the student of natural science to claim his place in this examination. If he is a medical student and is drawn by the examination to the study of one or two subjects which fall rather under *belles lettres* than within the

Digitized by Google

scope of his professional curriculum he may not have reason to regret his decision, even should he not be successful. Wider reading, more liberal interests, and some sound pretensions to culture are just what most of our students of medicine especially stand in need of at the present day.

What has been said applies still more forcibly to "students of science"—those studying for B.Sc. and similar examinations—in our various colleges. The published reports of the examination during the last four years prove unmistakably that the character of the examination and the advantages of the service are to them practically unknown. And yet the science man is usually also a mathematician; he prides himself on *knowing* his physics, his chemistry, his geology, and his botany; he should be able to write a tolerable essay on one of the three or four themes prescribed with commendable catholicity of choice; he is not generally a "duffer," and he should be able to find in the long list of the examination subjects one or two subsidiary ones by which to make success assured. Let him do so.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Musical Festival.

THE proceeds of the triennial musical festival go to the General Hospital and form a substantial element in the funds of that charity. This year the programme was arranged for the 5th, 6th, 7th, and 8th of the present month. There was a large attendance, favoured by fine weather, and the highest musical talent. The total receipts amounted to £13,874 4*s.* 11*d.*, being £635 more than the last festival. It is estimated that the sum of £5000 will be handed over to the new hospital committee; it will be gladly welcomed in the face of the numerous and heavy expenses incurred in the removal from the old building.

Sudden Death of Dr. F. W. Barry.

Dr. Barry, senior medical inspector to the Local Government Board, was found dead in a bedroom of the Grand Hotel this morning. He was expected at the parish offices for official purposes and left word to be called at 7.30 in the morning; no reply being received to this summons the room was entered, when Dr. Barry was found lying upon the floor dead and cold. An inquest will be held in due course. Dr. Barry's high attainments in sanitary science and his ability as an administrator will cause his death to be deeply regretted apart from the sad circumstances of its suddenness.

Midland Medical Society.

The inaugural meeting of the present session is announced for the 21st inst., when Sir Richard Thorne Thorne will deliver an address on "Soil and Circumstance in their Control of Pathogenic Organisms." It is expected that a large gathering will be present.

Death of the Coroner for South Staffordshire.

Mr. Edwin Hooper, whose death occurred on Oct. 3rd at the age of sixty-six years, held the office of coroner for South Staffordshire for a period of thirty-seven years, and for the borough of West Bromwich since it was constituted a county borough. For some years Mr. Hooper had been the subject of cancer of the tongue, for which he had undergone several operations. His death finally was attributable to pneumonia. It is estimated that he held over 13 000 inquests during his tenure of office. His duties were conducted with dignity and clearness of judgment. Already there are several candidates in the field, two of whom are medical men practising in the locality.

A Sad Coincidence.

An inquest was recently held on the body of a boy, aged seven years, whose death occurred under singular circumstances. The child came with his father and mother into the town. In a crowded street the father was knocked down by a cab; in the confusion which followed the child was run over by a cart and killed—a disastrous ending to the visit.

The Workhouse Infirmary.

An unpleasant incident has led to the resignation of the infirmary management committee. For a long time the committee state that they had felt that they had not the confidence of the board in their authority over the scrubbers and charwomen employed. These servants number about forty and are paid at the rate of 2*s.* a day, the annual sum for scrubbing alone amounting to about £1200.

Oct. 12th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Large Gifts to Owens College.

THE half-yearly meeting of the Court of Governors of Owens College was held on the 5th inst., when the chairman, Mr. Alderman Joseph Thompson, who regretted the unavoidable absence of the Duke of Devonshire, said that he had three very important and gratifying announcements to make. Mr. R. C. Christie, for long a member of the Court and the Council of the college and one of its most generous benefactors through his gift of the building of the Christie Library, had now given one-third of the balance of the estate of the late Sir Joseph Whitworth—as one of the three residuary legatees—amounting to not less than £50 000, and probably somewhat exceeding that sum. It would enable the Governors to complete the quadrangle and erect a college hall. The chairman further announced that two friends of the college who did not for the present wish their names to appear had offered through the Principal sums of £10,000 and £5000, the first for the erection, and the second towards the maintenance, of suitable buildings for the physical laboratory of the college. A further sum of £5000 would be needed to provide fully for the maintenance of the laboratory, and this the chairman hoped the college would in some way obtain. Another very welcome gift had been made by Mr. Edward Holt, one of the city councillors, who had given £1500, the cost of the new gymnasium. In a resolution thanking the donors of these munificent gifts, moved by Sir Ughtred Kay-Shuttleworth and seconded by the Principal (Dr. Ward), hopes were expressed that the council would take steps "to associate the name of Mr. Holt in some permanent manner with the new gymnasium." A resolution was also moved by Sir W. H. Houldsworth, M.P., and seconded by Sir Henry Roscoe, expressing the great regret of the Court at the "impending resignation of the distinguished principal of the college, Dr. A. W. Ward," and desiring to place on record its sense of "the immeasurable value of his services for more than thirty years as professor and eight years as principal." Mr. Alfred Neild and Mr. Thorburn supported the resolution, the latter speaking as a representative of the *alumni* of the college.

Salford Board of Guardians.

At the last meeting of the Salford guardians it was resolved: "That in future, with the consent of the Local Government Board, the period of training for probationer nurses be three years instead of two as heretofore, and that the scale of payment be as follows—viz., first year, £8 8*s.*; second year, £12 12*s.*; third year, £15 15*s.*" At 2 P.M. the meeting was made special to consider the best means of relieving the congested state of the workhouse and infirmary. Mr. H. Jenner-Fust, jun., general inspector of the Local Government Board, and Mr. W. M. Moorsom, assistant general inspector, were present. After some discussion it was resolved: "That a new workhouse be at once proceeded with, and the Sheffield system of scattered homes for children be adopted experimentally." In the course of the discussion Mr. Jenner-Fust addressed the board in favour of a new workhouse—for which, indeed, the land has been bought—and discountenanced the amalgamation of the workhouse and infirmary, and said that the epileptics should be lodged in new blocks. He also advocated entirely separate management for the two institutions. He was in favour of cottage homes—which one of the guardians characterised as "nothing better than juvenile workhouses"—where they had 370 children to deal with. The resolution was carried by 9 votes to 5.

The Police and First-aid.

Since 1891 it has been made a condition of service in the Manchester police force that applicants should pass an examination as to proficiency in the work of first-aid. The order was not made retrospective, so that many of the men have have not passed this examination. The week before last certificates for proficiency were given by the Lord Mayor to a number of the men. Out of 44 entitled to the certificate 41 were present. There are now in the force 771

Digitized by Google

of a possible 1037, or 74·3 per cent., who have passed the examination. This scheme might well be adopted all over the country. It would often be the means of saving life or limb, it would give increased interest to the work and tend to raise the tone of the men, and so ameliorate the policeman's lot which, it is said, "is not a happy one."

Unsound Meat in Salford.

A butcher in Salford was summoned to the Salford Police Court the other week for exposing for sale meat unfit for human food. The veterinary surgeon and meat inspector for the corporation said that he found eight pieces of meat exposed for sale which were quite unfit for food, and they were destroyed by order of a magistrate. The interest of the matter lies in this: that the defendant told the witness he bought the meat at the abattoir and gave 2*d.* a pound for it. According to the report there was no contradiction of this statement, and if the corporation abattoir was meant it suggests culpable laxity in supervision.

The Unsolved Sewage Question.

The majority of the members of the Manchester City Council visited the sewage works at Davyhulme yesterday week, at the invitation of the rivers committee, with the object mainly of seeing for themselves that the committee had done all that was practicable with the facilities at their command to purify the sewage of the city. Up to the present time the sum of £207,485 has been spent at Davyhulme, including the expenditure on the tanks and equipment, works in progress, and £24,500 for the new sludge steamer. There were differences of opinion expressed on the various schemes; some were in favour of the culvert, some were for deferring the matter for six or twelve months, and others, notwithstanding the object-lesson at Davyhulme, which was to have converted them, still maintained their opposition to the culvert. At a meeting of the rivers committee letters were read from eminent engineering experts who were, of course, in favour of the culvert, for it would be impossible for the engineering mind to resist the bewitching vision of a great sewer sixteen miles long. On the same day a meeting of the Mersey and Irwell joint committee was held, at which Mr. Killick, chairman of the consulting sub-committee, replied to a speech of Alderman Joseph Thompson at a meeting of the city council in which he had complained of the harsh treatment of the corporation by the committee. Mr. Killick said that Manchester had been treated like Salford, Bolton, Bury, &c., but had been granted extra time. He said, also, that it was a mistake to say that it was out of the power of the rivers committee to turn out a satisfactory effluent, for it had been done again and again when the sewage had been treated by precipitation and filtration. When precipitation alone had been used the effluents were much worse than the water of the Ship Canal into which they were turned. In connexion with the lamentations of Alderman Thompson, Mr. Killick made the suggestive remark that "it might be pointed out that Manchester had taken part in compelling authorities in the watershed to spend more money per head of the population than the highest estimates of the most costly schemes yet put forward for their own adoption." It should not be forgotten that Alderman Thompson is the vice-chairman of the Joint Committee, and so is not free from responsibility as regards this, and that he is chairman of the Rivers Committee of the Corporation, and so is in the interesting and perplexing condition of a man divided against himself. At a special meeting of the city council on Wednesday last a resolution in favour of promoting a Bill in the next session of Parliament authorising the construction of what a local paper calls "the great culvert" was adopted, there being three dissentients. The poll of the citizens is to take place about the end of the month and may lead to fresh developments.

Oct. 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal Commission on Tuberculosis.

THE Royal Commission on Tuberculosis paid a visit to Dublin on Oct. 12th and inspected the abattoir, the cattle market, and the fruit market. The members were received by Sir Charles Cameron and by the various officials connected with the markets, and were subsequently entertained at luncheon by the Lord Mayor at the Mansion House.

St. Vincent's Hospital, Dublin.

At the opening of the medical session at St. Vincent's Hospital on Oct. 5th Dr. Cox delivered an address on the grievances of army medical officers. Sir William Thomson, in moving a vote of thanks to the lecturer, made some very interesting observations.

The National Hospital for Consumption for Ireland.

The Marchioness of Zetland and Lady Milton, accompanied by Mr. and Mrs. Frank Brooke, visited the National Hospital for Consumption for Ireland at Newcastle, Co. Wicklow, on Oct. 7th. The party travelled by special train from Shillelagh, where the Marchioness is at present staying with her daughter, Lady Milton. After minutely examining the arrangements of the hospital, with which they were much pleased, the visitors returned to Shillelagh.

Imprisonment of a Medical Man.

An event, happily of very rare occurrence in the medical profession, took place at Lurgan Quarter Sessions on Oct. 7th, when Mr. James Millen Moore, L.R.C.P. & S. Edin., was sentenced to be imprisoned for one month in Armagh Gaol for an assault upon a boy who was in his employment. It would appear that the boy—between thirteen and fourteen years of age—went into Mr. Moore's employment in August, 1896, when he was a year younger. Mr. Moore, being dissatisfied with his conduct, ordered the boy on one occasion to strip himself in an outhouse, where he was beaten by the medical man on the naked back with a cane or other weapon. On another occasion being dissatisfied with the lad—and apparently, as the county court judge stated, he had cause to be—Mr. Moore made the boy strip with the exception of his trousers and shoes and had him tied to a post and beaten in a very severe manner. It was stated that the medical man acted *in loco parentis*, and that his father had given him authority to punish the boy. The case came originally before the Lurgan magistrates, who by a majority sent it for trial to the quarter sessions, where the grand jury found a true bill. Mr. Moore pleaded guilty, and for the defence it was urged that the sum of £28 which he had paid to the boy's father and the serious effect which the incident and the prosecution would for years have upon him as a practitioner and a representative public man more than atoned for his indiscretion. The county court judge and the magistrates present had a long discussion in reference to the merits and demerits of the case and they did not arrive at a unanimous conclusion, and the judge said in announcing the decision that he did not concur with it. At the same time, he was bound to give effect to the view of the majority of the magistrates, and that was that Mr. Moore should be kept in gaol for one calendar month without hard labour. Two magistrates, it was announced, did not concur with the decision and thought that Mr. Moore should be let off with a fine. A majority of the magistrates, the judge said, thought a month's imprisonment would be sufficient, but in his opinion a fine or one month's imprisonment did not touch the merits of the case, and he himself would have given a heavier punishment.

Epidemic of Typhoid Fever.

At the present time there is a widespread epidemic of typhoid fever in Belfast, and a large number of cases are being treated in the Union Fever Hospital and in the Royal Hospital. One of the dispensary medical officers asked his committee for further medical assistance, which was granted, owing to the large number of cases in his district. The Public Health Committee of the city at a meeting on Oct. 7th advised that the water retailed from the Cromac springs had not improved in quality and was unfit for human consumption. They pointed out the necessity for the regular cleansing of cisterns in houses and instructed their sanitary officer to have them inspected. They appointed a sub-committee to confer with Dr. Lorrain Smith, lecturer on pathology at Queen's College, with a view to arranging for the examination of forms of food, drink, and secretions bacteriologically in order that the origins of diseases might by this means be traced. There is a strong feeling that the Belfast Water Commissioners should publish fortnightly or every month an analysis of the city water (as is done in other towns) for the guidance of the public.

Belfast Royal Hospital.

Mr. Thomas Houston, M.B., B.S. R.U.I., has been appointed assistant gynæcologist.

Belfast Lunatic Asylum.

At the usual monthly meeting held on Oct. 11th the new superintendent, Dr. Graham, in his report pointed out the want of baths, there being none whatever in either the male or female hospital and only four for the whole institution. The entire lavatory department is improperly constructed; there are no receiving, sorting, or airing rooms, and no disinfecting chamber; the washing machines are obsolete; and the drying closets are dangerous, so that if a patient tripped he or she would be burnt. The entire laundry department needs to be remodelled. The kitchen is unsuitably situated and deficient in culinary apparatus. There is no mortuary or proper receptacle for the dead. There is no telephonic, electric, or other mechanical means of communication between the medical officers' quarters and the hospital wards. A committee was appointed to look into the matter. A governor also suggested the desirability of giving the inmates better bread.

On the recommendation of the Lord-Lieutenant of the county the Lord Chancellor has appointed Mr. E. C. MacDowell, M.D. Dub., F.R.C.P. Irel., of Mall House, Sligo, a magistrate for the county of Sligo.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Pathogenic Rôle of the Dust in Living Rooms.

M. KELSCH and M. Simmonnin read before the Academy of Medicine an interesting communication upon the above subject. According to these observers, the floors of our dwellings are as fruitful and dangerous a cause of infection as drinking-water. As a matter of fact, with the exception of typhoid fever and cholera, which are almost always spread by means of water, by far the greater part of other common maladies, such as the eruptive fevers, diphtheria, pneumonia, and, above all, tuberculosis, almost always arise from germs preserved in dust, except when direct infection takes place. This view is specially applicable to dwellings where a number of persons gather together, such as public schools, workshops in large towns, hospitals, and barracks. There is always present in these surroundings the danger of a sudden outburst of infectious disease. Infectious epidemics which occur in barracks without having been imported from outside arise from the dust where lie hid germs from former epidemics, or those brought in by the shoes of men who have infected their foot covering from the dirt of stables or latrines. This theory is already a commonplace in military epidemiology. Everywhere the watchfulness of the commanding officer, guided and helped by science and the progressive zeal of the army medical department, pursues the solution of the double problem of the purity of water and the absolute asepsis of the "surfaces" on which live the bodies of men for whom he is responsible. The ideals of the "service de santé" with regard to inhabited places are backed up by sundry measures which no doubt have not yet arrived at perfection, but which surpass anything hitherto attempted with regard to this matter. Such measures are cleansing of the flooring which by age and long microbial infection is specially dangerous, or even relaying it according to special systems which afford facilities for rendering it aseptic; doing away with, or at least disinfecting thoroughly and often, the interstices between the planks; or finally making the planks impermeable by means of some substance which will at the same time fill up the holes and disinfect any dirt which may be lodged therein. Such are the means by which military hygiene carries on the strife, and not unsuccessfully, against the origins of disease in barracks. The rendering of planking impermeable has for some years past been carried out in a number of barracks, and many a proof exists as to the minimising of the chances of infection which this process offers. It has passed through the stages of doubt, the tentative stage, and that of careful study, and it is now decided that the best process is coal-tarring, a usage to-day widely spread throughout the army, for this method is the one that best reconciles the demands of hygiene with those of economy. "Coaltarisation" has had unfavourable criticisms here and there; but these are due less to the process itself than to its application by unskilled hands. The experience of the last ten years has served only to fortify the opinion of the military medical staff as to the pathogenic *rôle* played by the dust which lies hid in the planks. M. Laveran, who has been for many years a military medical officer, has given it as his opinion that "coaltarisation" is not enough and that the only real remedy is to do away with planking altogether.

The Serum Treatment of Leprosy.

Señor Olaya Laverde, of Bucadramanga, Columbia, has sent to the Academy a long communication on the serum treatment of leprosy. The method which he employs differs from that of the medical man at Bogota, inasmuch as he prepares his animals by means of subcutaneous injections of fluid from leprous tumours which have just been removed from patients in an active stage of the disease. These animals always experience a well-marked general reaction, which disappears completely at the end of from five to six days. The blood of these animals, drawn when they have fully recovered their health, is collected with antiseptic precautions and injected in the ordinary way; accidents incidental to the operation are unusual and unimportant. On the first injection the patients show a pronounced febrile reaction, with malaise, pain in the back and the abdomen, and sometimes diarrhœa; this reaction commences six hours subsequent to the injection, and after an interval varying from twelve hours to three or six days, according to the case, it terminates in copious perspiration, a general feeling of comfort, and recovery of appetite. The therapeutic results are very marked and extend to all the symptoms. The good effects on the nervous system, for instance, are shown by the disappearance of anæsthesia, wandering pains, palsies, and pains in the joints. The improvement in the condition of the mucous membrane is manifested by the renewal of nasal respiration, the disappearance of ozæna, anosmia, and blepharitis, and the healing of conjunctival and corneal ulcers. The results on the skin are that perspiration returns, the hair on the scalp, the chin, and the eyebrows grows afresh, extensive ulcers rapidly heal, and leprous nodules are absorbed. The bacilli which could formerly be found with ease in the parts of the skin infiltrated with leprous nodules also disappear. The duration of the treatment is from three months to one year at the most. The good effects observed have been fully maintained in sixty cases up to the present time, and six of the patients may be considered to be cured, as a year has now elapsed since their restoration to health, but time alone will show whether the success obtained is permanent, and whether the majority of the patients will be thoroughly restored to health or only improved. Ordinary therapeutic measures, such as the actual cautery, may be employed at the same time as the serum treatment; the patient's food and general hygiene should also be attended to. The author makes special reference to "lavages du sang," by which he means large injections either of normal serum into the cellular tissue or of artificial serum into a vein; these injections seem to be valuable adjuncts to the serum treatment.

The Charge Against a Medical Man.

Dr. Laporte will appear before the police-court in a few days on a charge of homicide by imprudence. The various medical societies of Paris continue to take the utmost interest in his case, the decision in which will be of much consequence to all surgeons and accoucheurs. The medical society of the seventeenth arrondissement, where Dr. Laporte lived, the society of the observatory, the society of French medical practitioners, &c., have signified their disapproval of the proceedings. Surgeons and accoucheurs have written to the ordinary newspapers giving accounts of situations similar to that in which Dr. Laporte found himself, and taking credit to themselves for acting as he did—that is to say, for making use in time of need of such every-day instruments as happened to be immediately available. This unanimity of the profession seems to have acted favourably on public opinion and to have diminished the hostility to medical men which has been so prominent in the newspapers for some time past. Dr. Variot, physician to the Hôpital Trousseau, has written a strongly-worded letter, which all the papers have published, and in which he blames the experts consulted by the magistrate for not having at the outset declared that the case was not one which called for the immediate arrest of the accused.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The White Death.

"LA Morte Bianca" is not likely to figure in the programme or the discussions of the Eighth Congress of Internal Medicine, which holds its sittings in Naples from the 20th to the 24th inst. And yet, all too prevalent as it is in Italy, it prevails in most typical form in Naples itself. "The White Death," less swift in operation than its "black" counterpart, numbers more victims in the long run, and, even when it does not shorten life prematurely, its "conditions precedent" do much to impair the survivors' organism and tell disastrously on his offspring. But whence the name and what does it connote? The name is given by Dr. Achille Spatuzzi, professor of hygiene in the Neapolitan School, and the fact it describes may be found in his fascinating if melancholy work, "Saggi di Demografia e d'Igiene per gli Ufficiali Sanitari" (Essays in Demography and Hygiene for Sanitary Officers). Another writer on the theme is a colleague of Professor Spatuzzi, also a physician, Dr. Colajanni, professor of statistics in the same seat of learning, and it is his most recent deliverance on it that now concerns me. Much talk, he says, in the press, among the public and in Parliament, has been caused by the "strage degli innocenti" (slaughter of the innocents) disclosed last summer in the Brefotrofio dell' Annunziata; but this mortality of illegitimate foundlings, he continues, prevails in Italy "sempre e dappertutto" (always and everywhere) and need not distract attention from the "total mortality of the people of Naples." While throughout the kingdom the death-rate conspicuously declines, as infective diseases are more and more successfully combated, "the general specific mortality of Naples among the great civilised cities remains characteristically unique." The mean death-rate in Italy—a mean which takes account of deaths by malaria, pellagra, and by the chronic malnutrition of so many unfortunate regions—has sunk in a few years from 29 per 1000 to below 26. That of Naples, on the other hand, from 1879 to 1895 shows but insignificant oscillations—from 31·9 to 29 3—"an oscillation," he says, "indeed insignificant, for no further back than 1893 there was a mortality of 30·6—indeed insignificant," he proceeds, "if we reflect that in the comparatively rich quarter of San Ferdinando it sank to 18·2—that is, to proportions approximating those of civilised capitals, while in the wretchedly poor quarter of San Carlo all' Arena from 1881 to 1892 it had risen from 27·7 to 32 1. The difference," continues Professor Colajanni, "in mortality between rich quarters and poor quarters is indeed deceptive, though well enough known; but it may be profitable to illustrate it for Naples in one of her exceptional moods. During the cholera visitation of 1884 in the rich quarter of San Ferdinando the mortality scarcely touched 26·2 (the present mean in Italy), while it reached 47·4 in the Vicaria, 59·7 in the Pendino, and 64·4 in the Mercato." But (the reader may interpose) "all this is death in general; how about the 'White Death'?" Let him hear Professor Colajanni: "The foreign visitor, comfortably lodged and entertained in the principal hotels, is as safe on the lovely Neapolitan bay as in any European city; infective diseases, to which the stranger is most liable, are steadily declining in Naples; typhoid fever, with the Serino aqueduct bringing in pure water in any quantity, has almost disappeared. But 'la morte bianca' which reaps its thousands in the Neapolitan slums is the death by inanition and exhaustion; it is the death by slow degeneration, by misery, by nutrition of the worst kind, and even that defective; it is the death preceded always by anæmia, by chlorosis, by 'dusky pallor,' it is this death which marks a steady rise. Take the following figures by way of proof. In 1873 the deaths associated with congenital deformity (*vizi di conformazione*) were 131; in 1896 they were 240. Again, the deaths by tuberculosis in 1873 were 1216; in 1896 they were 1812; this, too, with no corresponding increase of population to account for it" There you have the "White Death" according to Professor Spatuzzi and Professor Colajanni, eloquently indicating physical degeneration, general and progressive, going *pari passu* with the moral degeneration which yields precocious delinquency as well as adult crime so alarmingly. Leading up to "the White Death" is the malnutrition which, though copiously illustrated in the works of Somma, Spatuzzi, Manfredi, and other Neapolitan hygienists, does not detain Professor Colajanni, who hastens on to the "material conditions of habitation" under which the poor of Naples live or rather die. London, for example, has 196 inhabitants for each square kilometre. Paris 265, Rome 280, Turin 340, Naples 939 and in her Pendino quarter 1254! "There is no hyperbole," he adds, "in saying that the Neapolitan population lacks air, oxygen, light, and that it huddles together in houses which are not human dwellings, but wild beasts' lairs." The children who go from these dens to schools make little change for the better as to ventilation. Professor Fazio, in his report to the Minister of Public Instruction, describes these schools as no better than they were demonstrated to be by a lamented Neapolitan philanthropist, the common councilman, Signor Casini, "omicide, costituenti un' offesa alla civiltà ed all' umanità" (homicidal, constituting an offence to civilisation and humanity). Professor Colajanni, whom no one will suspect of reactionary sympathies, adds that sixty years ago the illustrious Dr. De Renzi (it is mostly the medical man who plays the philanthropist in Italy) protested against the "condizioni tristissime" (deplorable circumstances) in which Naples languished under the Bourbon, whose Government resolved itself into the three f's—"feste, farina, e forche" (entertainments, meal, and gallows). But he asks, Is she much better off now? The "gallows" has been abolished, "meal" is diminished to starvation point, the "entertainments" continue, mostly in the form of the unveiling of monuments to the "heroes of the revolution," whose "commemoration" has already cost the country milliards of lire. Be it the task, he concludes, immediate and effective of the new *régime*, whether parliamentary or municipal, to redress the balance in favour of "farina" at the expense of the "feste," confident that a better-fed, better-housed, better-clothed populace would be a worthier commemoration of those heroes than all the statues, memorial tablets, unveilings, and fireworks, rhetorical or pyrotechnic, with which it is vainly sought to scare the wolf of hunger from the house and the "White Death" from its inmates.

Oct. 10th.

Obituary.

FREDERICK WILLIAM BARRY, M.D., F.R.S. EDIN., D.P.H. CANTAB.

WE regret to announce that Dr. F. W. BARRY, the senior medical inspector of the Local Government Board, was found dead in his bedroom at the Grand Hotel, Birmingham, on Tuesday last. The deceased was born at Scarborough (where his father was a town councillor) in 1850. He received his medical education at Edinburgh University where in 1876 he graduated as M.D., and took up the subject of public health immediately on being qualified, receiving the Diploma in Public Health from the University of Cambridge in 1877. His first appointment was as medical officer of health to the Craven Combined District of Yorkshire, an office which he filled from 1878 to 1879. In 1880 he was sent to Cyprus as superintendent of quarantine and of the Sanitary Commission. Here he did an admirable and useful work, and the census of Cyprus which was taken in 1881 was almost entirely his work, as well as the report upon the sanitary condition of the island for 1881. In July, 1882, he commenced his term of office at the Local Government Board, and a little later was called to the bar from the Middle Temple, and in addition was elected a Fellow of the Royal Society of Edinburgh. He was also elected Examiner in Medical Jurisprudence and Public Health at the Edinburgh University, and at the time of his death filled the same office at Aberdeen University. He leaves a widow and two children, a son aged nineteen and a daughter aged ten years. Dr. Barry had a wonderful faculty for collecting statistics and drawing valuable conclusions from them—in fact, he was, as one of his colleagues has said, the head of the intelligence department of the Local Government Board. Among the various reports which he drew up, besides the ones we have referred to above, we may mention the one written in coöperation with Mr. T. Gordon Smith upon "Back-to-back Houses," printed in 1888, while two reports of

Digitized by Google

his which have become classical are the "Report on an Epidemic of Small-pox at Sheffield during 1887-1888" and the "Report on an Epidemic Prevalence of Enteric Fever in the Tees Valley during 1891." Other reports which were very valuable were those upon "Cholera in England and Wales during 1893," the "Report on the Western Diffusion of Cholera during 1893," and the "General Report on the Sanitary Survey of the Coast-line of England and Wales for 1893-1894." Dr. Barry was very thoroughly examined before the recent Royal Commission on Vaccination, mainly with reference to the Sheffield outbreak of small-pox; and in the final volume of evidence just issued will be found his exhaustive and convincing refutation of the criticism which Mr. Alex. Wheeler had made on his memorable Report.

Some twelve months ago Dr. Barry met with a serious accident while travelling in Yorkshire. He was passing through a low stone doorway and thinking he had got completely through, raised his head suddenly and struck it against the lintel. Unfortunately for himself he was not so stunned as to be unable to continue his work, which he did for some ten days, but at the end of that time he was compelled to take to his bed, as symptoms of serious injury to the upper part of the vertebral column appeared. For some sixteen weeks he was kept in bed with his head and upper part of the spine kept completely at rest by means of sand bags. He was absent from his work for about seven months altogether, but had apparently completely recovered. Dr. Barry's loss will be severely felt by all his colleagues at the Local Government Board. He was extremely popular and kindly, a very hard worker, and a very charming colleague to work with.

The inquest was held on Wednesday last before Mr. Bradley, the Birmingham coroner, when the jury returned a verdict of death from natural causes.

EDMUND PERCIVAL FRANCE, M.R.C.S. ENG., L.R.C.P. LOND.

THE death of Mr. E. P. France occurred on May 20th, at Port Darwin, in Australia. Mr. France was surgeon on the Eastern and Australian Company's s.s. *Menmuir*, having left England in March, 1896, in the s.s. *Australia* of the same company. Returning to the *Menmuir* with some passengers on the night of May 20th the gangway to the ship was found to be very steep owing to the great fall of tide. According to the *Hong-Kong Telegraph*, from which we quote, Mr. France slipped from the gangway and fractured his skull against the wharf, death ensuing soon afterwards. Mr. France was educated at University College, London, where he held the appointment of assistant to the Professor of Physiology (Mr. Schäfer), with whom he did valuable research work on the brains of monkeys, the results of which were published in the Transactions of the Royal Society. In 1890-91 Mr. France was house surgeon to the North-Eastern Children's Hospital. In 1892 he was appointed principal medical officer to British North Borneo, a position he held for three years. In March, 1896, he joined the Eastern and Australian Company's steamers and remained with them till his death. His firm but kindly manners made him many friends and he was much esteemed by his patients.

JOHN COMELY WICKHAM, L.R.C.P. LOND., M.R.C.S. ENG., L.S.A.

MR. WICKHAM, who died at his residence, Gordon House, Tetbury, Gloucestershire, on Sept. 30th, in his ninety-fifth year, was by many years the oldest resident in the town and was long and affectionately known as "old Dr. Wickham." He received his medical education at St. George's Hospital, London, taking the M.R.C.S. Eng. qualification in 1825 and the L.R.C.P. Lond. and L.S.A. in 1843. Fifty years ago Mr. Wickham went to Tetbury from Didmartin. He was formerly medical officer to the Tetbury Cottage Hospital and to the Tetbury Dispensary. Mr. Wickham will be much missed by his numerous friends and acquaintances in Tetbury and the surrounding district.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Rafael Branchat y Vime-Prada, Professor of Hygiene in the Granada Medical School.—Dr. Jean-Baptiste de Mayer, formerly a much respected Antwerp practitioner, at the age of eighty-two years.—Professor Max Burchardt, Directing Surgeon of the Ophthalmic Department of the Charité Hospital, Berlin, on Sept. 25th from a pulmonary affection at the age of sixty-six years. While serving in the army, from which he recently retired with the rank of surgeon-general, he was stationed for a time at Königsberg, and he there attached himself to the university as *privat-docent*. His original work was carried on first on dermatological matters and afterwards in ophthalmology. He devised an erecting ophthalmoscope and published papers on the determination of the acuteness of vision and on the detection of malingering amongst soldiers by pretence of bad sight.—Dr. Hjalmar Heiberg, whose death is announced at the age of sixty years, was in early life a marine surgeon and after his return to Christiania acted as assistant to Professor Wruge in the Anatomico-pathological Institute of the University, becoming afterwards Professor of Pathological Anatomy. He conducted valuable researches on the bacteriological causes of puerperal fever and pyæmia, and published a book on the subject in the German language.—Dr. Edmund Drechsel, Professor of Physiological Chemistry in the University of Berne, who was formerly a lecturer in Leipzig, died suddenly from heart disease in Naples, whither he had gone to work in the Marine Zoological Station.—Professor Lopold Auerbach, of Breslau, whose death has been announced, was in his seventieth year. He was a pupil of Purkinje and carried on many researches of a physiological and anatomical character. His name is known to every medical student in connexion with the plexus mesentericus or Auerbach's plexus. He also published papers of great originality on the early determination of sex, on amœbæ, and on the physiology of muscle.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In the primary examination the following candidates have passed in the subjects indicated:—

PART I.

Biology.—H. M. Huggins, St. Bartholomew's Hospital.
Chemistry.—J. Freeman, Bristol; F. B. Hargreaves, Manchester; and K. Heanley, Royal Free Hospital.
Materia Medica and Pharmacy.—A. E. Gilford, R. Gillett, C. Hind, H. M. O. Jones, and D. E. Lockwood, Royal Free Hospital; L. R. Marshall, St. Mary's Hospital; L. S. Molony and F. M. Payne, Royal Free Hospital; and H. F. Stilwell and R. Storrs, St. Bartholomew's Hospital.

PART II.

Physiology.—N. C. Beaumont, St. Bartholomew's Hospital; T. Burdekin, University College Hospital; J. D. Graham, Belfast and Glasgow; K. E. Gregg, Royal Free Hospital; N. Hodgetts, Birmingham; B. Holroyd, Leeds; A. D. Nicolson, Glasgow; J. Notley, Birmingham; L. W. Roberts, Cambridge; H. M. Serjeant, Royal Free Hospital; L. S. Shoosmith, St. Mary's Hospital; and F. W. Whyte, Belfast.
Anatomy.—W. P. Allen, Birmingham; J. R. Bentley and M. B. Dawson, Middlesex Hospital; J. D. Graham, Belfast and Glasgow; A. T. Harvey, London Hospital; N. Hodgetts, Birmingham; B. Holroyd, Leeds; F. J. F. Jones, Guy's Hospital; H. G. Lewer, Edinburgh; A. D. Nicolson, Glasgow; J. Notley and S. Page, Birmingham; L. W. Roberts, Cambridge; H. M. Serjeant, Royal Free Hospital; and L. S. Shoosmith, St. Mary's Hospital.

UNIVERSITY OF GLASGOW.—The following have passed the First Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated (B., Botany; Z., Zoology; P., Physics; C., Chemistry):—

Thomas Anderson (B., C.), William Archibald (B., C.), William Armitage (B.), John Stoddart Barr (B., P.), Thomas Thompson Bathgate (Z.), George Thomson Bogle (B., P.), William Macalister-Brown (B., C.), John Joseph Burke (B.), Hector Charles Cameron (B., P.), Robert David Campbell (B.), Daniel Lyall Carmichael (Z.), Edward Seymour Chapman (B., Z., P.), Walter Bartlett Chapman (B., P.), George Herbert Clark (B., P.), James Bertie Wylie Cook (B., P., C.), Samuel Campbell Cowan (B., P.), James Craig (B., Z.), Ernest Hamilton Cramb (Z., C.), Andrew Currie (B., C.), John Shedden Dale (Z., P.), David Beattie Davidson (B., P., C.), Gregor Hugh Grant Davie (B., Z.), James Dick, M.A. (B., C.), Hugh M'Millan Donaldson (P.), Andrew Robertson Dow (B., Z.), George Horn Downie (B., C.), Reginald Nairn Dunlop (B., C.), George Ferguson (Z., P.), Gilbert Garrey (Z., C.), David George Somerville Gartshore (P., C.), William Gemmill (B., Z., C.), William White George (Z.), John Ritchie Gilmour (B., Z.), William Girvan (C.), George Gordon (B., P.), John Miller Gordon (B.), Archibald Gow (B., C.), Andrew Parlane Granger (B., C.), John Guthrie (B., P.), George Pillans Harlan (B., P.), Saul Hyman Harris (P.), Francis

Joseph Henry (B., C.), Charles Milburn Hope (B., P.), Douglas William Hunter (B., Z., P., C.), Neil M'Coll Hutchison (Z.), William Johnstone Isbister (B.), George Rutherford Jeffrey (B., P.), Daniel Ross Kilpatrick (P., C.), Alexander King (B.), John Lambie (B., Z., P.), Robert Lauder (Z.), Alexander Linn (B., Z., P., C.), Frank Lochrane (B., P.), John Lockhart (B., C.), Alexander Logan (Z., C.), William Jamieson Logie (B., C.), Joseph Paterson Lusk (Z., P.), Edward Magoveny (B., C.), William Alexander Masson (B., Z., P., C.), Robert Menzies (B., P.), James Grant Millar (B., C.), Robert Joseph Mills (B., C.), William Alexander Milne (B., C.), John Morison (P., C.), Allan Howie Muir (B., C.), John Muir (B., Z.), Coll Macdonald (B.), Daniel Douglas M'Dougall (B.), William Ferguson M'Glashan (B., Z., P., C.), Thomas M'Laren (B., Z.), Alex. Maclean (P., C.), Hugh Archibald M'Lean (B.), Alexander M'Gaw M'Millan (P., C.), James M'Pherson (Z., P.), James Roy M'Vail (B., P.), John Dunn Nisbet (C.), John Paton (C.), Alexander M'Millan Pollock (P.), James Nimmo Prentice (P.), Thomas Hood Rankin (P.), Peter Mackenzie Reid (C.), Thomas Richmond (Z., P., C.), William Robertson, Kilmarnock (B., C.), Thomas Ritchie Rodger (B., Z.), William George Rodger (B., C.), Norman Cumming Rogers (B., Z.), Andrew Taylor Ross (B., C.), Charles James Ross (Z., C.), David Sandler (B., P.), Frank Donald Scott (Z.), James John Sinclair (B., Z.), Malcolm Bernard Gathorne Sinnette (B., C.), Donald Steel (B.), John Strathearn (B., C.), Robert Rennie Swan (C.), James Nathanael Todd (B., C.), Joseph Goodwin Tomkinson (B., C.), John Wright Turner (B., C.), John Unsworth (Z.), Robert Warden Valentine (B., C.), William Dinning Walker (B.), George Smith Wallace (B., C.), Thomas Irby Wallace (B., P.), Hugh Fleming Warwick (Z., P.), John Forrest Weston (Z., C.), David Ashley Wilson (Z., C.), David Watson Wilson (C.), John Wilson (B., C.), Thomas Watson Wilson (P., C.), William Webster Watt Wilson (P., C.), William Robertson Wylie (Z., P., C.), James Wyper (Z.), John Young, Bearsden (C.), John Young, Glasgow (B., C.), and Watson Young (B., P.). Women—Margaret Edith Bryson (B., Z.), Minna Edgar (B., Z.), Helen Mary Gordon (C.), Isabel Hill (Z.), Janet Thomson Miller (P., C.), Alice Moorhouse (B., Z.), Jessie Seath M'Ewen (B., Z.), Mary Janet Pirret (B. Z.), Mary Ann Thompson Ritchings (B.), Elizabeth Ness MacBean Ross (B., Z., P., C.), Martha Hunter Scott (B., Z.), Agnes Bankier Sloan (B., Z.), Elizabeth Macfarlane Sloan (B., Z.), Edith Christine Wallace (B., Z.), and Henrietta Fraser Young (B., Z., P.).

The following have passed the First Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

Robert Cumming, B.D., and William Henry Ferran.

The following have passed the Second Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated (A., Anatomy; P., Physiology; M., Materia Medica and Therapeutics):—

James Freeborn Bennett (M.), William Broad (A., P., M.), Andrew Brownlie (M.), Thomas Bullough Calland (A., M.), Thomas Carruthers, M.A. (A., P.), James Robert Chalmers (M.), David Maclure Cowan (A., P.), John Craig (A., P., M.), George Morris Crawford (A., P.), William Crerar (P., M.), Charles Peter Garvie Crichton (A., M.), Charles Cheven Cumming (M.), James Austin Dickie (P.), Frank Lindsay Dickson (M.), David Curr Douglas (P., M.), James Drummond (M.), Hugh Campbell Ferguson (M.), George Gardner (A., P.), John Gardner (A., P.), George Garry (M.), William Gibson (M.), Hyam Goodman, M.A. (M.), Archibald Wilson Harrington (A., P., M.), Isaac Mackay Huey (M.), Thomas Inglis (A., M.), Nicol Jamieson (M.), Andrew Kerr (M.), Andrew Love (A., P., M.), Ramsay Millar (P., M.), Hugh Miller (M.), Norman M'Leod Miller (M.), Ebenezer Mitchell, M.A. (A., P.), Daniel Morrison (A., P.), Alexander MacCulloch (A., P., M.), James Hogg Macdonald (M.), Peter M'Fadyen (M.), John M'Gilchrist (M.), Anderson Gray M'Kendrick (A., P.), Charles Forbes Maclean (P., M.), George Todd Maclean, M.A. (A.), Norman Forbes MacLeod (M.), William Johnston Maclure (A., P.), John M'Millan (M.), Thomas Neill (A., P.), John Patton (M.), Thomas Stephens Picken (A., P.), John Reid, Lanark (A., P., M.), Robert Rennie (A.), William Alexander Riddell (M.), Arthur Robin (M.), James Scott, M.A. (M.); James Shearer (M.), Andrew James Smith (A.), David James Smith (M.), William Stewart Stalker (P., M.), Peter Alexander Steven (M.), Alfred George Stewart (M.), Frederic Richardson Stewart, M.A. (A., M.), James Douglas Brownlee Stewart (M.), Robert Taylor (A., P.), Charles Pinkerton Thomson (M.), William Brown Thomson (P., M.), Thomas Bird Tierney (A., P., M.), Joseph Swinburne Townley (A., P.), Arthur Vost (A., P., M.), Alexander Laurie Watson, M.A. (A., P. M.), Alexander Simpson Wells, M.A. (M.), Robert Orr Whyte, M.A. (A., P., M.), Alexander Wilson (A., P.), William Wright (P., M.), and John Doctor Young (M.). Women—Auguste Boyes (M.), Sarah Davidson (M.), Marjorie King Henderson Fleming (M.), Mabel Hardie (M.), Jessie Sophia Beatrix Hunter (A.), Ina Lochhead M'Neill (M.), Sara Maude Robertson (P., M.), Maud Spencer (M.), Gertrude Florence Fleetwood Taylor (P.), and Edythe Marjorie Stewart Walker (A., P.)

The following have passed the Second Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

Thomas Holmes, Richard Hewson Hunter, and John Joseph Lowell.

The following have passed the Third Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subject or subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

Robert Fisher Ballantyne (P., M.), James Barrowman (P., M.), William Bennett (M.), John George Wilson Boleyn (M.), John Brunton (P., M.), John James Buchan (P., M.), Ranald Douglas Campbell (P., M.), James Carruthers, M.A. (P., M.), Robert Carswell, M.A. (P., M.), John Ronald Currie, M.A. (P., M.), James Fulton Findlay (P., M.), Robert Fullarton, M.A. (M.), Alexander Garrow (M.), James Garden Green (M.), David Sloan Harvey (P., M.), Harold Smith Heap (M.), Ernest Frederick Lionel de Jersey (P., M.), Edward William Reese Jones (P., M.), Archibald Jubb (P., M.), Andrew Stewart Lang (P.), John Wilson Leitch M.A. (P.), Percival Ambler Mitchell (P., M.), Archibald Turner Macewan (P., M.), Dugald M'Kinlay (P., M.), Alfred Duncan Macnair (P., M.), William Gardner Neill (P., M.), Percival Lealie Pearce (M.), William Hart Steel, B.A. (P.), Francis Stevenson (P.), Frederick Ernest Stokes (P., M.), Thomas Morton Strang (P., M.), Andrew Taylor (P., M.), Henry Nisbet Turner (P., M.), Robert Andrew Hannan Watson (M.), and William Webster (P., M.). Women.—Mary Gardner (P., M.), Jane Lorimer (P.), Margaret Wallace Howie M'Neil (M.), Margaret Elizabeth M'Neill (P., M.), and Jean Effie Prowse (P.).

The following have passed the Third Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.):—

A, including Pathology.—William Kilpatrick Hutton, M.A., and Charles Edward Cortis Stanford, B.Sc.

B, not including Pathology.—Lionel Mitchell Mackay, and William Shearer.

THE GREIG SMITH MEMORIAL.—The sum of £458 has been already received towards raising a permanent memorial to the late Mr. Greig Smith. The amount still needed is about £400, and as the fund will shortly be closed it is hoped that further subscriptions will be sent at an early date to the treasurer, Mr. F. B. Girdlestone, 4, Downside-road, Clifton.

THE Forfarshire Medical Association held the usual quarterly meeting in the University College, Dundee, on Sept. 30th, Dr. Alex. Campbell, President, being in the chair.—Mr. Greig showed two cases after Fracture of the Neck of the Humerus. (*a*) A boy, aged thirteen years, fractured his humerus six months ago. Mr. Greig wired the fragments owing to the difficulty in these cases of keeping the ends in apposition with splints. The result showed free movement at the shoulder-joint. (*b*) A boy, aged thirteen years, fractured his humerus seven years ago, when it was treated with splints. The movement was impaired, due chiefly to contraction of the latissimus dorsi and teres major muscles, which were divided this year. Mr. Greig also showed a patient after Pyæmic Arthritis, with free movement at joints which had been affected.—Dr. Mackie Whyte showed a specimen of Carcinomatous Tumour pressing on the Superior Vena Cava and the Right Bronchus.—Mr. Greig showed two specimens of Tuberculous Bursæ removed from under the quadriceps extensor tendon in both cases, pointing out that by early removal of tuberculous bursæ tuberculous arthritis might be prevented.—Dr. Dickson (Carnoustie) read notes of a case of Vesical Calculus, illustrating the action of piperazin on vesical calculi. The patient, aged seventy-two years, had passed small calculi at intervals and suffered severe pain. He refused operative treatment, but was treated with piperazin, with the result that he improved, passing numerous small calculi at frequent intervals. Dr. Dickson suggested that the piperazin caused disintegration of the calculi by acting on the uric acid.—Dr. Templeman read notes on the Disinfection of Rooms by Spraying. The first dealt with disinfection by sulphurous acid gas, its disadvantages and possible inefficacy, as he said it had been proved that 4½ per cent. was incapable in twenty-four hours of killing spores and even bacilli in from six to eight hours. He recommended disinfection by spraying with a germicide as more efficacious. It caused no damage and the material used was non-poisonous. The substance he advocated was formalin (40 per cent.) with the Equifex sprayer. Several specimens of wall-paper which had been sprayed that morning were exhibited, and the sprayer was explained and used before those present.—Dr. Dickson and Dr. Miller said they were not prepared to give up sulphur without further proof.—Dr. Mackie Whyte read notes of a case in which Chyle had Transuded into the Pleural, Pericardial, and Peritoneal Cavities. The patient, a girl aged twenty-one years, had been under treatment previously for tuberculous glands in the neck. Between 500 oz. and 600 oz. in all were drawn off from the various cavities, reaccumulation quickly taking place. There was no necropsy, but it was believed the condition was due to obstruction of the thoracic duct near its termination. An analysis by Dr. Lockhart Gillespie showed 4 per *mille* of fat. The literature of the subject was reviewed and the case commented on in this light.—Dr. Mackness showed a Placenta from a case of Triplets in which labour was induced at the sixth month.—On the motion of the President the various speakers were accorded a hearty vote of thanks for their interesting papers.

UNIVERSITY COLLEGE, LONDON.—The following Medical Entrance Scholarships have been awarded:—131 guineas, Mr. J. E. Stratton; 55 guineas, Mr. J. D. Bolton; and 55 guineas, Mr. H. A. Lyth.

WE have been requested by the Registrar of the Royal College of Physicians of Ireland to state that at the monthly business meeting of the College, held on Oct. 1st the following resolution was adopted: "That the censure of the College be passed on Dr. C. L. Lumley, in consequence of his unprofessional conduct disclosed in the case of Balmer *v.* Balmer, Phillips, Lumley, and Rohe."

SANITARY MATTERS AT WHITCHURCH, SOUTH WALES.—At a meeting of the Whitchurch Parish Council, held last week, the members were quite indignant that the erection of an infectious diseases hospital should have been suggested, and in order to signify their disapproval of the proposed scheme the clerk was instructed to write to the several ground landlords asking them not to let any land as a site for such a building.

KING'S COLLEGE.—The following Entrance Medical and Science Scholarships have been awarded:—Medical Entrance: W. E. Blackall, 60 guineas. Sambroke Medical (Science): J. A. Drake, £50; and M. R. C. MacWatters, £50. Warneford Medical (Arts): H. B. Day, £25 for three years; and A. A. Myers, £25 for two years. Worshipful Company of Clothworkers (Science): E. Hinks, £30 for two years; and A. E. Ruffhead, £20 for two years. Engineering Entrance: G. H. Lovegrove, £15.

THE GLASGOW SOUTHERN MEDICAL SOCIETY: SESSION 1897-98.—The annual business meeting was held on Oct. 7th, Mr. Stuart Nairne being in the chair, when the following were elected:—President: Dr. James W. Allan. Vice-President: Mr. R. H. Parry. Treasurer: Dr. Yeo W. Thomson. Secretary: Dr. Wm. Watson, Gartmore, Langside. Editorial Secretary: Dr. Henry L. G. Leask. Sealkeeper: Dr. Alex. Roxburgh. Court Medical: Mr. Stuart Nairne, Dr. Alex. Rankin, Dr. Eben. Duncan, Dr. R. W. Forrest, and Professor James Dunlop. Extra Members of Council: Dr. J. Fraser Orr, Dr. Hugh Kelly, and Dr. T. W. Jenkins. Representative to Board of Victoria Infirmary: Profesor James Dunlop.

DISTRIBUTION OF PRIZES AT UNIVERSITY COLLEGE, LIVERPOOL.—Sir John Brunner, Bart., M.P. (in the absence of the Earl of Derby), distributed the prizes and certificates, on the 9th inst., to the successful students of the medical faculty of University College, Liverpool. The dean of the faculty (Dr. A. M. Paterson) read the annual report of the work of the session, a summary of which appeared in THE LANCET of Aug. 14th. The first award of the new Robert Gee Fellowship in Anatomy, a prize of the value of £100, was made to Mr. W. Graham, M.B., Ch.B. Vict. Mr. Edward Lawrence, who occupied the chair, commented on the prosperous condition of the medical school compared with that of other departments of the college, which were sorely in need of funds.

LITERARY INTELLIGENCE.—The works recently published by Mr. H. K. Lewis, of Gower-street, include the thirteenth edition of the Handbook of Therapeutics, by Dr. Sydney Ringer and Dr. Harrington Sainsbury; the fourth edition of Dr. Aldersmith's Ringworm and Alopecia Areata; the fifth edition of Dr. L. C. Parkes' Hygiene and Public Health; Manuals of Obstetric Practice and of Gynæcological Practice by Dr. D. A. Dührssen of Berlin (translated by Mr. J. W. Taylor and Dr. F. Edge); Dr. William Gray on Influenza; and the Sanitary Inspectors' Handbook, by Mr. Albert Taylor. Mr. Lewis also announces for early publication a Handbook of Diseases of the Nervous System, by Dr. C. E. Beevor; the fifth edition of a Practical Text-book of the Diseases of Women, by Dr. A. H. N. Lewers; and Mastoid Abscesses and their Treatment, by Dr. A. Broca and Dr. F. Lubet-Barbon (translated by Dr. H. J. Curtis).—A new weekly medical journal has just appeared in Breslau entitled *Wochenschrift für Therapie und Hygiene des Auges*, which is to deal entirely with the treatment and hygiene of the eye. This would seem to most of us to be a somewhat limited field for a weekly journal, but the learned editor, Dr. Wolffberg, of Breslau, and the eminent staff who are to coöperate with him—amongst whom we notice the names of Professor Cohn, of Breslau, and Dr. E. Jacobson, of Berlin—have doubtless taken good care to inform themselves of the probabilities of success before embarking on such a serious undertaking as that of a weekly publication.

THE Corporate and Medical Reform Committee have received from Sir William Thomson and Mr. George Brown, Direct Representatives of the profession for Ireland and England respectively on the General Medical Council, favourable replies concerning a programme of reform suggested by the committee.

THE Water Committee of the Council for the Borough of Hastings (which includes St. Leonards-on-Sea) state that samples of the water supplied to the borough have just been submitted to the analysis of Dr. Dupré, who reports that the waters "are in every respect admirably adapted for a town supply, both as drinking water and for general domestic use."

DIPHTHERIA IN LONDON.—The deaths from diphtheria in London, which had been growing in numbers week by week during September, having been 25, 35, and 45 in the three weeks ended on the 25th, showed still further increase in the seven days to Oct. 2nd, during which they totalled 49, although even then they were 3 below the corrected decennial average for the thirty-ninth week of the period 1887-96. The Camberwell sanitary area had 6 deaths, Hackney and Lambeth each 5, Battersea 4, and Kensington and Bethnal Green areas each 3 deaths credited to them in the week. Only one of the 49 deaths was in an infant, other 26 were of children under five years of age, and 2 of persons aged upwards of twenty years. The admissions to hospital in the week were 165, and 1039 cases remained under treatment in hospital at the close of the week. In the Outer Ring there were 14 deaths registered from diphtheria, including 5 of persons belonging to West Ham and 3 to Edmonton registration districts. Last week there were as many as 53 deaths from diphtheria registered in London, 49 being the corrected decennial average for the particular week. Hackney had 6 deaths, Poplar and Lambeth each 5, Kensington 4, and Bethnal Green and Wandsworth sanitary areas had each 3 deaths credited to them. Not one death occurred of an infant or a person aged over twenty years, and 37 were of children aged one to five years. The admissions to London hospitals numbered 157, and 1050 patients were under treatment in these institutions on Saturday last. In the Outer Ring 13 deaths were registered from the disease, 7 being in West Ham and 4 in Hendon registration districts. Thus, we seem to be face to face with an increasing autumnal mortality from this malady in and around London.

Appointments.

Successful Applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BENNETT, F. DILLON, M.R.C.S., L.R.C.P., L.S.A. Lond., has been appointed Junior Medical Officer to the Army and Navy Coöperative Societies, vice Stanley De Butts, resigned.

BRADBURY, J. B., M.D., F.R.C.P. Lond., has been appointed Assessor to the Regius Professor of Physic at Cambridge University.

UNIVERSITY OF SYDNEY, New South Wales, Australia.—Demonstrator of Physiology. Salary £350. Passage money allowed, £60. Applications to the Acting Agent-General for New South Wales, Westminster Chambers, 9, Victoria street Westminster.

WEST LONDON HOSPITAL, Hammersmith-road.—Assistant Physician.

Births, Marriages, and Deaths.

BIRTHS.

ANDERSON.—On Oct. 9th, at Hoghton-street, Southport, the wife of G. Reinhardt Anderson, F.R.C.S., of a daughter.

BROOKE.—On Oct. 10th, at Buxton House, West Bridgford, Notts, the wife of Frederick Brooke, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

FORBES.—On Oct. 9th, at Drumminor, Calverley-park, Tunbridge Wells, the wife of Norman Hay Forbes, of Forbes, F.R.C.S. Edin., L.R.C.P. Lond., of a daughter.

LAMBE.—On Oct. 11th, at West Bridgford, Notts, the wife of Thomas Lambe, M.R.C.S., L.R.C.P., of a daughter.

WOOD.—On Oct. 5th, at Darnaway-street, Edinburgh, the wife of Russell E. Wood, M.B., F.R.C.S. Edin., of a daughter.

MARRIAGES.

BEAN—RIGG.—On Oct. 12th, by licence, at St. Edmund's Church, Salisbury, by the Rev. Arthur Jeffreys Douglas, Louis C. Bean, M.R.C.S. Eng., L.R.C.P. Lond., youngest son of Alfred C. Bean, of Hanwell, to Lucy M. Le Blond Rigg, of Tavistock, youngest daughter of the late Rev. William Rigg, M.A., D.D., formerly of Kingston-on-Thames.

BLUMER—KITCHING.—Oct. 7th, at St. Maurice's Church, York, by the Rev. T. L. Brashaw, M.A., vicar of Wortley, brother-in-law of the bride, assisted by the Rev. H. Robinson, M.A., rector of the parish, Frederick Milnes Blumer, B.A., M.B., of Stafford, third son of Luke Blumer, M.D., of Sunderland, to Isabel, eldest daughter of the late Rev. Robert Kitching, M.A., vicar of Westow, Yorks, and of Mrs. Kitching, West View, Bootham-crescent, Yorks.

BROOKE—SWABEY.—Oct 6th, at St. Thomas à Beckett, Bath, by Rev. Stephen Swabey, B.A., assisted by Rev. Maurice Swabey, M.A., Gilbert Edward Brooke, B.A. Cantab., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., L.S.A. Lond., of Bayfield House, Bath, to Alice Marie, fourth daughter of Rev. H. B. Swabey, M.A., Chaplain to R. U. Hospital, Bath.

SIMMONS—HIGGINBOTHAM.—At Christ Church, Sutton, on Saturday, Oct. 9th, by the Rev. J. R. Courtenay Gale, Gerald Allpress Simmons, M.D., B.S. Lond., to Ann, third daughter of the late John Edwards Higginbotham, of Glasgow, and Mrs. Higginbotham, of Meadowcroft, Sutton, Surrey.

DEATHS.

DRING.—On Oct. 5th, at West View, Seaford, Herbert Johnson Dring, M.B., M.Ch., in his 39th year.

LUPTON.—On Oct. 8th, at Waterhead, Oldham, James Lupton, L.S.A., of Brookhurst, Stockport-road, Ashton-under-Lyne. Interred at Dukinfield Cemetery on Tuesday, Oct. 12th. Friends please accept this intimation.

MCWATT.—On Oct 11th, at Haymount, Duns, N.B., Robert Charles Mc Watt, M.D., L.R.C.S., aged 69 years.

WICKHAM.—On Oct. 7th, at Gordon House, Tetbury, John Comely Wickham, L.R.C.P., M.R.C.S., and L.S.A., aged 94 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (20th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), ing's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (21st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (23rd).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (19th).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. J. F. Payne (President): Introductory Address.—Dr. G. F. Still: The Bacteriology of the Simple Posterior Basic Meningitis of Infants. Specimen:—Mr. C. Spurrell: A Case of Multiple Spontaneous Fracture. Card Specimen: Dr J. Calvert and Mr. Strangeways Pigg: A Case of Melanotic Sarcoma. Mr. D'Arcy Power: Empyema of the Antrum in a Child aged eight weeks.

WEDNESDAY (20th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Mr. T. Comber: The Limits of Species in the Diatomaceæ.

MEDICAL SOCIETY OF UNIVERSITY COLLEGE (London).—8 P.M. Annual Public Night. Dr. W. B. Ransom: Vis Medicatrix Naturæ. Exhibition of Microscopes, Drugs, Instruments, Roentgen Rays, Chromoscope, &c.

THURSDAY (21st).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-sq., W.).—8 P.M. Card Specimens:—Mr. A. Frost: Odell and Porter's Centring Instrument for Ophthalmic Lenses.—Mr. A. Lawson: Leuco-sarcoma of Choroid.—Dr. Rayner Batten: (1) Foreign Body on Optic Papilla; (2) Pulsating Tumour of Orbit. 8.30 P.M. Mr. H. R. Swanzy (President): On some Congenital Anomalies of the Eye, as illustrated in the Society's Transactions. (Introductory Address) Papers:—Mr. E. Clarke: Some Experiments on the Union of Corneal Wounds.—Mr. T. Bickerton: Spontaneous Dislocation of the Lens into the Anterior Chamber: Replacement by Operation.

HARVEIAN SOCIETY.—Ordinary Meeting. Dr. Clifford Beale: Recent Experience of the Use of Creasote in Phthisis; Clinical Cases.

FRIDAY (22nd).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 30 P.M. The following cases will be shown:—Dr. St. Clair Thomson: (1) Very Distensible Nævus of the Frontal Region, with Defect in the subjacent Bone in a Man aged fifty years; (2) A Young Woman with Primary Tuberculosis of the Interior of the Nose and Secondary Infection of the Pharynx, with microscopic specimen.—Dr. B Abraham: Hemiplegia in a Child aged two years.—Dr. J. K. Fowler: A Case of Functional Tremor. Patients in attendance at 8 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

TUESDAY (19th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Ferrier.

HOSPITAL FOR NERVOUS DISEASES (73, Welbeck-street).—Dr. T. D. Savill: On the Clinical Investigation of Disorders of the Nervous System.

WEDNESDAY (20th).—HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Habershon: Angina Pectoris.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—Mr. S. Paget: Surgical Cases.

NORTH-WEST LONDON CLINICAL SOCIETY (North-West London Hospital).—8.30 P.M. Sir William Broadbent: Annual Address.

THURSDAY (21st).—THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Voelcker: Demonstration of Selected Cases.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"A PREDISPOSITION TO HERNIA?"

To the Editors of THE LANCET.

SIRS,—Will you allow me to reply to the letter in THE LANCET of Oct. 9th, signed "The Father, M.D."? I have conducted a large general practice for thirteen years in the Australian bush, where hard riding is the rule. Children, one might almost think, were born on horseback. Bare-backed or in the saddle the Australian child is at home on the horse at a much younger age than his. I have had every opportunity of observation, and during those thirteen years not one single case of inguinal hernia in children has come under my notice. Further, I am the medical referee for ten Australian Life Offices, and have not had a case of hernia to report upon for any one of them. I do not wish to say that hernia does not exist in Australia, but merely confine my remarks to his question—viz., horse-back exercise. The public are always fond of talking upon subjects they know nothing about. I think your correspondent need not trouble about his little child. But if still in doubt, and before making a change, it would do no harm to allow the boy to wear a properly-fitted truss as a means of precaution, though I consider it unnecessary. Enclosing my card, which is at your correspondent's service.

I am, Sirs, yours faithfully,

Oct. 12th, 1897. COO-EE.

Nurse.—We do not prescribe or recommend treatment or individual practitioners. Surely our correspondent must know a medical man whom she can consult.

THE UNQUALIFIED ASSISTANT.

To the Editors of THE LANCET.

SIRS,—Will you kindly give publicity to the following? On July 27th last my wife gave birth prematurely to a son, since which time he has been attended at different times by the assistant of a local medical practitioner, which assistant I believed to be a fully-qualified medical man. On Sept. 29th the child died while still under his care, he having been summoned to him only the day before his death. I reported the death at the surgery, and was informed for the first time that the said assistant was unqualified, and that therefore a certificate could not be granted until the coroner had been communicated with. I was also informed that I had no right to assume that he was a fully-qualified practitioner. The police visited my house to make full inquiries respecting the child's death. This has caused me much pain, annoyance, and trouble, after having done all in my power to save the child's life. Holding a public position, I shall be glad if you will kindly advise me through the medium of your journal as to what course I should take in order to remove from the minds of my neighbours and the public any misgivings which may arise respecting the child's death. Trusting something may be done in order to prevent the practice of unqualified men attending cases of illness and putting the public to the same inconvenience that I have been subjected to,

I am, Sirs, yours faithfully,

WM. IVE TUCKER.

Farnham-terrace, St. Mary's-road, Ilford, E., Oct. 7th, 1897.

*** We agree with our correspondent that the public ought to be informed when the assistant is not qualified.—ED. L.

Verax is recommended not to have anything to do with the matter.

AN UNFORTUNATE CIRCULAR.

WE have received the wrapper which is sent out, we are informed, upon a preparation known as Fearnley's Sedative Pomade. The wrapper bears a testimonial from a medical man speaking highly of the efficacy of the preparation. "I have used it myself," says the medical man, "and have prescribed it for my patients with equal benefit," and his full name and address, qualifications, and past and present honorary positions are appended. We strongly advise this medical man to approach the enterprising hairdresser and perfumer with a view to the suppression of the unprofessional circular.

Sigma would be glad to hear of a home where an epileptic boy aged thirteen years could be received for half a guinea a week. Address letter to THE LANCET Offices.

Interested has omitted to give us his name and address.

"THE GENERAL PRACTITIONER AND THE 'NURSES' COÖPERATION.'"

To the Editors of THE LANCET.

SIRS,—We beg to call your attention to the misleading character of the above headline in your issue of last week. The Nurses' Coöperation, 8, New Cavendish-street, was founded in 1891, and incorporated in 1894, and has over 400 nurses on its staff, but it has no branches or other offices. It is therefore an obvious injustice to the fully-trained experienced nurses of the Nurses' Coöperation to have the title which belongs exclusively to them used as a heading to a paragraph about a private institution. We have no "midwifery branch," although we supply certificated nurses for maternity cases. Our scale of fees and other particulars are shown in the annual report enclosed herewith. We shall be greatly obliged by your inserting this letter in your next issue, as the comments made in THE LANCET of last week might give your readers an erroneous opinion of the aims of this society. We have from the first worked with and under the doctors, not in opposition to them; and in return we have received from them most generous support and appreciation.

I am, Sirs, yours faithfully,

H. F. GETHEN, Secretary to the Nurses' Coöperation.

The Nurses' Coöperation, 8, New Cavendish-street, W., Oct. 12th, 1897.

To the Editors of THE LANCET.

SIRS,—In answer to "General Practitioner's" remarks, will you assure him that although we are fully qualified midwives (I personally hold three certificates), and most grateful to the London Obstetrical Society for having raised the standard of a midwife's work and education, we have no intention or desire to infringe or impose on our superior officers' rights; instead of so doing we are prepared to call in any specialist in midwifery who would attend or general practitioner who lives in the neighbourhood of any patient we may attend should the slightest complication arise. The time has not arrived, however, I fear, when a woman could be allowed to do what is essentially a woman's work without calling upon herself undeserved rebuke. It is impossible for the busy family practitioner, kind-hearted and long-suffering as he often undoubtedly is, to do the work we do, for in many cases fever, or perhaps something worse, would have followed had we not previously well cleansed the patient; and, again, in nearly all cases (we only attend respectable married women) the mother has not only to be attended to, but her gruel, &c., prepared, and the baby is also generally washed for several days. Personally—and I believe every woman with proper feeling will express the same sentiment—I should be very sorry to undertake any responsibility my capabilities will not allow me to do safely. Instead of injuring any professional gentleman we have been the means often, not only of saving years of suffering, but of upholding the doctor, for it is no unusual thing to be accosted with, Can you tell me what to do for such and such a thing or such a person? And the reply has always been to the effect, Go at once to a good doctor and get reliable advice, pay a reasonable fee if you can, and be sure you follow his directions. As to any professional gentleman connected with this institution dodging to obtain another practitioner's patients I must be allowed to say that in all our work, both public and private, we have only met one professional gentleman who has in any way forgotten that he is a gentleman (this does not apply to your correspondent), and we have met with so much real kindness from both specialists and general practitioners that rather than cause any feeling of jealousy or idea of unjust dealing I am prepared to give up the work we so much like—that is, midwifery amongst the respectable poor, who so greatly need our assistance in their hour of trial. At the same time, permit me to assure "General Practitioner" that there is no medical officer here who would act as he describes, for no matter what the world may think we only wish to fulfil our contract with the public.—viz., send out reliable, trustworthy nurses, and do good where it may be done without either professing to be what we are not or injuring in any way those who, in any hour of need, are self-forgetful and always hard-worked and badly paid. If your correspondent will call upon me I shall be pleased to assure him of our coöperation with, not against him.

I am, Sirs, yours faithfully,

Oct. 10th, 1897. MATRON.

To the Editors of THE LANCET.

SIRS,—I omitted to send you one of our midwifery cards yesterday, and upon again referring to the advertisement in THE LANCET I see the Marylebone people have left out "*diploma*," also I see your correspondent, in speaking of our work, says, "*inadequate*" services. This I deny. Our services have hitherto been not only adequate, but most successful, for we have never had a torn perineum or dead baby or fever; and our patients not only get up well, but remain well. Kindly make what use you please of this communication, which can easily be verified.

I have the honour to be, Sirs, yours truly and obliged,

M. CANNING, Matron, L.O.S.,

(A midwife and nurse of twenty years' experience).

New Bond-street, W., Oct. 11th, 1897.

A newsagent has sent us the following for insertion: "In answer to an address of loyalty and congratulation addressed to the 'Queen' by the matron and nurses of Ings House Nurses' Coöperation, 81, New Bond-street, W., the following reply was received:—

"Whitehall, 4th October, 1897.

"MADAM,—I have had the honour to lay before the Queen the loyal and dutiful address of the matron and nurses of the Ings House Nurses' Coöperation on the occasion of Her Majesty attaining the sixtieth year of her reign, and I have to inform you that Her Majesty was pleased to receive the same very graciously.

"I have the honour to be, your obedient servant,

(Signed) "M. W. RIDLEY."

*** We have received the above four communications concerning a paragraph which appeared in THE LANCET last week. Disregarding the fourth—for we have not impeached the loyalty of Ings House—we must point out that the questions that have been asked remain for the most part unanswered. We have not suggested that nurses have no place by the lying-in bed, but only that the advertisement which we quoted attempts to exclude medical men therefrom. We note without enthusiasm that the services of Ings House are only at the beck and call of respectable married women. The title of our paragraph was suggested by the advertisement under consideration. We have before us printed matter showing that the Ings House institution styles itself "Nurses' Coöperation," but it seems from Miss Gethen's letter that they have not the earliest claim to the title.—ED. L.

M.B.—Is not our correspondent a little quick to smell evil? A's conduct looks to us like that of an off-hand and busy but perfectly honourable man.

J. S. G. (Bristol) should consult his medical attendant.

A DANGER OF THE ANASTOMOSIS BUTTON.

IN the *Edinburgh Medical Journal* for September, 1897, Mr. H. J. Waring records the following case. A patient suffered from a malignant growth which involved both the small intestine and the transverse colon. Both were resected and the divided ends united by anastomosis buttons. On the third day there were symptoms of intestinal obstruction and the patient died. At the necropsy each button was found completely blocked with orange pips, three being fixed in the larger and two in the smaller. To prevent such an accident the writer advocates the use of a button of larger lumen made of decalcified bone, and so capable of being dissolved by the intestinal juices. He prefers the shape recommended by Mr. Bailey.

AN INTERESTING CASE.

To the Editors of THE LANCET.

SIRS,—Kindly allow me to publish the following case for the benefit of young practitioners who are in doubt as to the respective merits of version and forceps in deformed pelvis. A woman, aged twenty-five years, was delivered four years ago of a living child by forceps—a difficult operation. About two years ago she was again delivered by forceps of a dead child. The operation was more difficult and more painful to the woman. On Aug. 28th I saw her at 3 A.M., and found the funis prolapsed on the thighs and the os fully dilated. Having during the preceding few months performed version three times for arm presentations, and the patients mending well, I thought that it might suit her better than forceps. I introduced my hand into the uterus, but the patient screamed, held herself rigid, &c., so that in less than two minutes I withdrew my hand and suggested $CHCl_3$. An elderly friend of mine who has a great partiality for version came to see the patient, so I gave two and a half drachms of chloroform, and he turned; from beginning to finish he was nearly three-quarters of an hour, and he said that the head was impacted, and he had to use very great force and jaw-traction to deliver. Little hæmorrhage followed. The pulse was about 100, rather small at the finish. The patient came round and talked to us before we left her at 5 o'clock. She had immediately after recovery from the chloroform excruciating pain, and after 7 o'clock began to roll about the bed in agony. When I got there a little before 8 o'clock she was dead. Looking back at the case I wish that, seeing that the funis was pulseless, I had perforated the head and extracted by forceps as I consider the patient died from the shock and injury of the version. In the first two parturitions I did not give chloroform. The projection of both the pubes and the sacrum into the pelvic cavity was very well marked. The patient was rickety with small, much-bowed legs, and a large well-developed body.—I am, Sirs, yours faithfully, J. C.

* * The case would appear to have been one of ruptured uterus.—ED. L.

C. G. G.—The Act says that the guardians *may* with the consent of the Local Government Board pay to medical officers reasonable compensation for extraordinary services, and in the scale of prices simple fractures of the thigh or leg are put down at £3. As the word used is "may" we suppose the guardians may be within their legal right in refusing payment, but even then we presume they would have to give reasons. We advise our correspondent to write to the Local Government Board, giving a clear statement of his case, and we feel sure that that department will see justice done.

"ADVERTISING EXTRAORDINARY."

IN reference to some remarks made by us recently concerning the application for the post of surgeon to the G.W.R. Provident Society by a Dr. William Polson a correspondent has sent us the circular advertisement of a "Dr." A. Hands, another and also unsuccessful competitor for this appointment. Mr. Hands holds the qualifications L.R.C.P., M.R.C.S., but in the circular to the voters he gives himself a medical degree and includes a reproduction of his photograph. If the wording of Mr. Hands's advertisement is not as offensive as that of Dr. Polson—and it is not—the circular still remains a very regrettable production, and neither gentleman can be held in the least degree excusable because of the methods of the other.

M.B., C.M.—"Gas referees" have been appointed under the following Acts: The City of London Gas Act, 1868; The Gaslight and Coke Companies Act, 1876; The South Metropolitan Gaslight and Coke Companies Acts, 1869 and 1876; The Commercial Gas Act, 1875, and The Gaslight and Coke and other Gas Companies Acts' Amendment Act, 1880. The clause under the heading of "Sulphur Compounds other than Sulphuretted Hydrogen" reads thus: "The maximum amount of sulphur with which gas shall be allowed to be charged shall be 17 grains of sulphur in every 100 cubic feet of gas." This order emanates from the following address—17, Buckingham-street, Adelphi, W.C., and is dated March, 1889. Further information could doubtless be obtained at the gas-testing offices of the London County Council, Spring-gardens.

THE LIABILITIES OF A BONE-SETTER.

To the Editors of THE LANCET.

SIRS,—I should be glad to know whether a bone-setter is liable to damages for mal-practice in the same way as a medical man is, or whether any distinction is made by the courts of law?

I am, Sirs, yours faithfully,

Oct. 10th, 1897. INQUIRER.

*** The bone-setter is certainly liable for damages, but usually escapes such prosecutions. The patient having lost his money, and not having regained his health, does not care to expose his folly publicly. Where a patient, on the other hand, thinks he has a chance of proving mal-practice against a registered medical man, so far from being deterred by the fear of the ridicule of his neighbours he is spurred on to legal action by the certainty of their sympathy.—ED. L.

THE DOLOMITE ALPS.

To the Editors of THE LANCET.

SIRS,—Can any of your readers give me any information concerning the value of a sojourn in the district of the Dolomite Alps, Austrian Tyrol, for malarial fever?

I am, Sirs, faithfully yours,

Oct. 10th, 1897. B. D.

Mr. F. H. Madden.—The Spas and Mineral Waters of Europe, by Hermann Weber and F. Parkes Weber (London: Smith, Elder, and Co.); Bradshaw's Dictionary of Mineral Waters (London: Kegan Paul, Trench, Trübner, & Co.); Annuaire des Eaux Minérales (Paris: Publishing office of *La Gazette des Eaux*); Allgemeine und Specielle Balneotherapie, by Karl Grube (Berlin: Hirschwald); Balneotherapeutisches Lexicon, by E. H. Kisch (Vienna and Leipzig: Weber und Schwarzenberg).

NEGLECT OF VACCINATION IN ISLINGTON.

IF Islington is again overtaken by one of those great epidemics of small-pox which have affected it more than once in the last twenty-seven years it will not be the fault of its indefatigable medical officer of health, Mr. Alfred E. Harris. Mr. Harris has just published some statistics which may well alarm the public of this great parish. These figures show that there has been a steady increase in the neglect of vaccination during the last twelve years, so that, whereas in 1885 of 9683 children born only 8·0 per cent. were finally unaccounted for, in 1896 of 9752 children born no less than 22·4 per cent. are unaccounted for. Such wholesale violation of law is doubtless the fault of the guardians more than of the inhabitants. It is nothing short of a scandal that a board of guardians should override the wisdom of the Legislature. The vestry of Islington has very properly protested against the guardians being in this matter the sanitary authority. One thing, however, is clear, that if at the approaching election of guardians this question is not put into the very front of those on which the election will turn the inhabitants will then become responsible for the unprotected state of the children and for general treason to the teachings of science and of common observation.

Nemo.—1. Storage and exposure to air will remove iron as will also sand filtration. 2. It is the duty of the sanitary authority to see that every place under their supervision has a fairly pure and wholesome supply of water. On the representation of any person to any local authority that within their district the water in any well, tank, cistern, or pump is so polluted as to be injurious to health such authority may apply to a court of summary jurisdiction for an order to remedy the same and may make an order directing the well, tank, cistern, or pump to be permanently or temporarily closed, or such other order as may appear to them to be requisite to prevent injury to the health of persons drinking the water; and the court may, if they see fit, cause the water complained of to be analysed at the cost of the local authority applying under the section. 3. Since the above are provisions in the Public Health Act, clearly the medical officer of health in considering the quality of the water-supply is only carrying out a public duty to report from time to time his opinion as to its fitness or unfitness for drinking purposes. This being so he is surely beyond the pale of private legal action.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Newcastle Chronicle, Luton Reporter, Isle of White Observer, Batley Reporter, Express and Star, Manchester Courier, Temperance Record, Wilts Standard, South Wales Daily News, Birmingham Post, Western Morning News, East Anglian Daily Times, Dunstable Advertiser, Times of India, Pioneer Mail, Norfolk Chronicle, East Essex Advertiser, Liverpool Daily Post, Architect, Scotsman, Builder, Northampton Mercury, Sussex Daily News, Bedford Standard, Sussex Express, Sheffield Telegraph, Portsmouth Times, Brighton Gazette, Leicester Post, The Universe, Bristol Mercury, Derbyshire Times, Hereford Times, Worcester Herald, Dundee Courier, Leeds Mercury, Cambs Times, Kidderminster Times, Weekly Echo, Devon Gazette, Yorkshire Post, Sanitary Record, Lincolnshire Echo, Eastern Post and City Chronicle, City Press, Hertfordshire Mercury, Weekly Free Press and Aberdeen Herald, Reading Mercury, Mining Journal, Local Government Chronicle, Surrey Advertiser, Public Health, Engineer, Local Government Journal, Bath Herald, Bath Chronicle, Cape Argus, Craven Herald, Kentish Observer, Daylight, Wigan Examiner, Thanet Guardian, Cable, Le Temps (Paris), Eastern Post and City Chronicle, West Middlesex Herald, Denbighshire Free Press, &c., &c.*

UNDER EMINENT SCIENTIFIC CONTROL.

"APENTA"

THE BEST NATURAL APERIENT WATER.

Bottled at the Springs, Buda Pest, Hungary.

"We know of no stronger or more favourably-constituted Natural Aperient Water."

L. Liebermann

Royal Councillor, M.D., Professor of Chemistry, and Director of the Royal Hungarian State Chemical Institute (Ministry of Agriculture), Buda Pest.

OBSERVATIONS IN PROFESSOR GERHARDT'S CLINIC IN THE CHARITE HOSPITAL, BERLIN.

A translation of the Report upon some experiments that have been made under the direction of **Professor Gerhardt** (see BERLINER KLINISCHE WOCHENSCHRIFT, March 22nd, 1897), demonstrating the value of **Apenta Water** in the treatment of **Obesity** and its influence on change of tissue, can be obtained on application to the address given below.

THE LANCET says;—"A much-esteemed purgative water."—"**Its composition is constant.** The practitioner is thus enabled to prescribe definite quantities for definite results."

The BRITISH MEDICAL JOURNAL says;—"Affords those guarantees of uniform strength and composition which have long been wanting in the best-known Hungarian Waters."

"An ideal purgative."—PRACTITIONER.

APPROVED BY THE ACADÉMIE DE MÉDECINE, PARIS.

Considering the well-known nature of the Hungarian Bitter Water Springs, it must obviously be desirable for the medical profession and the public to be assured authoritatively that the working of the Springs from which Apenta Water is drawn is carried on in a scientific manner; and with this view it is **placed under direct independent scientific and hygienic control and supervision.**

P. B. BURGOYNE & CO.'S

AUSTRALIAN WINES.

TINTARA (FERRUGINOUS)

and Harvest Burgundy.

In BOTTLES and FLAGONS.

From THE LANCET.

"**TINTARA.** It is a dry, non-acid, satisfying Wine, and might take the place of Port Wine. By analysis, the constituents of grape juice abound, the phosphoric acid is particularly high, while the Wine is remarkably free from sugar."

From the MEDICAL TIMES.

"The **TINTARA** is a Natural Wine of generous quality, is grown on ferruginous soil, and possesses high tonic and invigorating properties. The Wine before me is quite mature, pre-eminently full-bodied, and nutritious."—Dr. D——, M.R.C.P., F.R.C.S.

AS EVERY DAY DINNER WINES THEY HAVE NO EQUAL IN FLAVOUR & ROBUSTNESS FROM ANY PART OF THE WORLD.

FROM EVERY WINE MERCHANT and GROCER in the KINGDOM.

CHAMPAGNE.

ABSOLUTELY FREE FROM SUGAR.

THE LANCET, January 13th, 1894.—"Apart from its freedom from sugar, this wine contains also a wholesome and palatable proportion of the acid constituents of the grape, a feature of some importance also to the diabetic patient, since it has been observed that light acid wines exercise a powerful retarding influence on salivary digestion, impeding the digestion of starchy materials and the consequent production of sugar. It is a brilliant, sparkling wine, possessing all the agreeable qualities of a high-class champagne, and yet one which may be taken, according to our analytical observations, in approved quantity where strong alcoholic and saccharine drinks are prohibited."

The BRITISH MEDICAL JOURNAL, January 20th, 1894.—"It has long been the crux in dieting diabetic patients or rheumatic and gouty persons, or those tending to excessive obesity, to enable them to include in their dietary any form of champagne or other sparkling wine, most of which are heating and heady, and more or less loaded with partially fermented saccharine. The 'Champagne-Sans-Sucre' (Laurent-Perrier) which Messrs. Hertz & Collingwood, 38, Leadenhall-street, have submitted to us, justifies its name under analysis, and is free from these defects."

THE character of this Wine—the first **NATURAL CHAMPAGNE** produced, and **ACCEPTED BY THE MEDICAL PROFESSION** and the public as an agreeable and innocuous beverage,—is now so well established that it is only necessary to remind those who desire to prescribe or consume a completely fermented and wholly unadulterated juice of the grape of its special qualities.

THE PROPRIETORS GUARANTEE that it is **NATURAL** in the full sense of being produced by the simplest process, and not in any way sophisticated either before fermentation or bottling. There is absolutely no added liqueur or sugar of any description: and the saccharine elements of the pure grape-juice are as thoroughly as possible fermented out.

The **LAURENT-PERRIER CHAMPAGNE** may therefore be confidently recommended and used in every case in which a first-class wine of the kind is deemed desirable.

Sample Bottle for examination will be sent free to any practising member of the Medical Profession on receipt of his card. Medical Men who desire this Wine for their own use would oblige by writing for the special professional quotation to the

Sole Proprietors, HERTZ & COLLINGWOOD, 38, Leadenhall Street, London, E.C.

Hunyadi János

A VERY INTERESTING and important contribution on Natural Mineral Waters of the purgative saline type was published in the report of a Special Analytical Commission in THE LANCET of December 5th, 1896. This report is made all the more interesting and reliable from the fact that a LANCET Commissioner personally visited the Saxlehner Springs, near Buda Pesth, and obtained samples on the spot, which were subsequently analysed in THE LANCET Laboratory, and the results obtained compared with samples purchased at a number of shops in London. The results showed that **HUNYADI JÁNOS, the Prototype of all Bitter Waters,** was, wherever it might be obtained, a water showing a **perfect uniformity of composition,** and one that could be **relied upon absolutely** as at **all times being identical** with that drawn from the Spring and fountain head. The numerous analyses in THE LANCET Report give very striking evidence not only of the **honesty of the water,** but bear out also the **remarkable uniformity of composition** that has characterised **HUNYADI JÁNOS** for **a third of a century.** Thus, the results recently obtained in THE LANCET Laboratory accord exactly with those obtained in Liebig's Laboratory over thirty years ago. **Nothing could be more satisfactory than this from the therapeutic point of view. Practitioners can thus depend** upon the water they prescribe, and may be assured that when **HUNYADI JÁNOS** is administered the **medicinal effects will always be the same,** and **with the same good results.** As is pointed out in the Report, an important feature in **HUNYADI JANOS** Water is the constancy of ratio of the active saline constituents to each other. The sodium and magnesium sulphates are together in almost exactly equal proportions, so **that what therapeutic property is lacking in the one is balanced by the other.** Neither the sodium sulphate nor the magnesium salt are in excess of each other. **In this way the purgative effect is not drastic,** but **mildly yet decidedly effective.** Again, besides these chief medicinal salts there are present in important quantity also in **HUNYADI JÁNOS** Water, Sodium Chloride, **Sodium Carbonate,** and **Lithium Chloride.** It cannot be doubted that each of these constituents contributes towards the **favourable action of the water,** which has for so long been a **distinctive and satisfactory feature attending its administration.** Last, but by no means least, the report of THE LANCET Commission shows that **HUNYADI JÁNOS** Water is bottled under **admirable sanitary precautions.** In the details of the analyses given there was not the slightest indication that **HUNYADI JÁNOS** Water contained any objectionable organic matter from whatever source. While therefore the medicinal properties of **HUNYADI JÁNOS** as a natural aperient are **sure and reliable,** it is **safe** also from the very important fact of its **extreme organic purity.**

Hunyadi János

PROPRIETOR

ANDREAS SAXLEHNER, BUDAPEST.

HARVEY'S
SUGAR-FREE PALE ALE.

(Protected by Her Majesty's Royal Letters Patent.)

The only **ALE** which may be drunk with impunity by persons with whom, from various causes, ordinary Beer does not agree.

We are now able to place before the Medical Profession and the public

A PERFECTLY PURE BEER,

Brewed from the choicest MALT and HOPS. In every respect a high-class Pale Ale, excepting only that it is

ABSOLUTELY FREE FROM SUGAR.

Mr. T. FAIRLEY, Leeds City and County Analyst, F.R.S. Edin., F.C.S., F.I.C., certifies June 3rd, 1896, that this Pale Ale is

"ABSOLUTELY FREE FROM FERMENTABLE SUGAR."

For further analyses see THE LANCET, May 22nd, 1897, and "The British Medical Journal," April 24th, 1897.

An article in THE LANCET says:—"During the last ten months it (the SUGAR-FREE PALE ALE) has been tried in one patient who had consulted me for lithæmia, two cases of chronic muscular rheumatism, one case of chronic gout, one case which I believe to be uric-acid headache, and one case of chronic rheumatic arthritis (in addition to the case of this complaint mentioned below), besides a large number of persons who, though healthy, cannot take ordinary ale. In none of these instances has it been followed by any pain, stiffness, lethargy, headache, or any of the ill effects which follow the use of ordinary beers or wines."—THE LANCET, August 14th, 1897.

SPECIAL TERMS allowed to the MEDICAL PROFESSION, to whom a Sample Bottle will be sent free upon application.

The Sugar-free Pale Ale is supplied upon receipt of Cheque or Postal Order, in "Imperial" half-pints. Price 4s. 6d. per dozen. Cases and Bottles charged 3s. per dozen extra, which amount will be refunded in full upon return of empties.

TO BE OBTAINED THROUGH ALL WINE AND SPIRIT MERCHANTS, OF

Messrs. BURGOYNE & CO., 12, Coleman Street, E.C.,

And of HARVEY & CO., PELLON BREWERY, HALIFAX.

VIROL

is an Ideal Form of Fat Food for Children and Invalids.

It is composed of Red and Yellow Bone Marrow, combined with the fats and proteids of raw eggs, active Malt Extract, &c., in a ratio in accordance with physiological principles, and is a very pleasant form of administering natural Iron and Fat.

MARROL

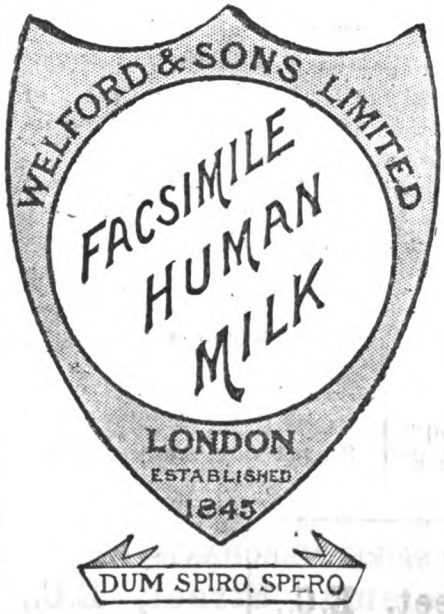
is a most agreeable substitute for Cod Liver Oil for Adults.

It is prepared from Ox-bone Marrow, Extract of Malt, &c., and does not cause dyspepsia or any digestive derangement.

As fatteners both VIROL and MARROL supersede Cod Liver Oil, whilst their attractive flavour enables them to be eaten on toast, or in a variety of ways, replacing unpleasant medicines by a Food Luxury.

MANUFACTURED BY

BOVRIL LIMITED, LONDON,



Food Specialists, Contractors to Her Majesty's and Foreign Governments, &c.

CHAIRMAN—THE RIGHT HON. LORD PLAYFAIR, G.C.B., LL.D.

CONSULTING CHEMISTS—PROFESSOR SIR EDWARD FRANKLAND, K.C.B., M.D., Corr. Mem. French Institute; WILLIAM HARKNESS, F.I.C., F.C.S., F.R.M.S., 40 years Food Analyst to H.M. Government.

MILK PREPARATIONS & NURSERY SUPPLIES

From WELFORD & SONS (Dairy Company)

ARE THE BEST AND MOST RELIABLE from the fact of being prepared from Perfectly Fresh Milk, produced on their own Farms (within 20 minutes' drive of the Chief Dairy).

FACSIMILE HUMAN MILK.

The perfection of "Humanised Milk." The best substitute for, and strictly analogous to, the NATURAL MILK OF MOTHERS, being the result of a series of investigations in feeding the Cows to produce a Milk specially adapted to the "Humanising" process.

PEPTONISED MILK.

For Weak or Impaired Digestions.

STERILISED MILK.

Safe! Handy!! Reliable!!! Invaluable for the Home, Seasi Voyages, or temporary Country Residences.

SPECIAL NURSERY SUPPLIES, *including—*

PURE FRESH MILK from our own Dairy Farms;
ASSES' MILK from our own Herd;
GOATS' MILK, &c., &c.

Also SWEET WHEY, BUTTERMILK, KOUMISS,
SENT OUT IN PATENT STOPPERED BOTTLES.

Orders to Chief Dairy & Offices, ELGIN AVENUE, MAIDA VALE, LONDON, W.

BAYER'S PHARMACEUTICAL SPECIALITIES

TRIONAL. A most reliable and quickly acting *hypnotic* of the Sulphonal group. Dose: 16 to 20 grains, in a large cup of hot liquid.

TANNIGEN. An almost tasteless astringent. Most efficacious in Chronic, Acute, and Summer Diarrhœas. Adult dose: 8 grains every three hours.

SALOPHEN. Specific for Influenza, Headache, Migraine, Acute Articular Rheumatism, Chorea, Sciatica. Dose: 15 grains four to six times daily, in powders, &c.

LYCETOL. Tartrate of Piperazine Antilithic Uric Solvent. Has a marked effect on the diuresis. Dose: 16 to 32 grains daily.

SOMATOSE. A tasteless, odourless, nutrient meat powder; it contains all the albuminoid principles of the meat in an easily soluble form. It has been extensively employed and found to be of the greatest service in consumption, diseases of the stomach and intestinal tract, chlorosis, and rickets. It is of great value in convalescence from all diseases. Somatose supplies all the protein matter required by the body, it strengthens the muscles and stimulates the appetite in a remarkable manner. Dose for adults: a level teaspoonful 3 to 4 times a day with milk, gruel, coffee, &c.

IODOTHYRIN. The active principle of the Thyroid Gland. It is most efficacious in Strumous Diseases, Myxœdema, Obesity, Rickets, Psoriasis, Eczema, and Uterine Hæmorrhages. Dose: 5 grains two to eight times a day for adults; 5 grains one to three times daily for children.

ARISTOL. An Iodine Cicatrisant which is an excellent odourless substitute for Iodoform, and highly recommended for Burns, Wounds, Scrofulous Ulcerations, &c.

EUROPHEN. A perfect substitute for Iodoform. Odourless and non-toxic. Has a covering power five times greater than Iodoform. Especially useful in Ulcus Molle et dur.

LOSOPHAN. A cresoltrisiodide particularly efficacious in the treatment of all kinds of cutaneous disorders caused by animal parasites.

PHENACETINE-BAYER, SULFONAL-BAYER, PIPERAZINE-BAYER, SALOL-BAYER.

Samples and literature may be had on application to the Wholesale Depôt for all "Bayer's" Drug Specialities:—

ELBERFELD FARBENFABRIKEN CO., LTD., 19, ST. DUNSTAN'S HILL, E.C.

Also at MANCHESTER, GLASGOW, and BRADFORD.

CELERINA.

W. P. England, M. D., White Pine, Pa., says: I have used Celerina and am pleased to say that in all cases of nervous prostration, such as follows the use of alcohol, and for all cases of nervous debility, I find it without an equal. After the experience I have had with it I do not hesitate in recommending it to the profession as one of our best nerve tonics.

The action of Celerina on the brain and nervous system is that of an exhilarant and slight narcotic, relieving depressions and lessens irritable nerve conditions. In cases of organic and functional lesions of the heart, an increased steadiness of pulse-beat and diminution of pulse irritation is apparent.

A. J. Wesco, M. D., Seven Mile, O., says: I have tested Celerina and got good results. Man, aged sixty-five years, mechanic, habits very intemperate, will spree for weeks, came to me with nervous system in bad fix; could not eat or sleep. Gave him eight ounces Celerina, teaspoonful three times a day, which placed him on his feet again, and for that I think it par excellence.

Convulsions may frequently be cut short, like magic, by teaspoonful doses of Celerina repeated at short intervals. The nausea as an after effect of chloroform or other narcosis, may generally be controlled in the same manner.

T. J. Haile, M. D., Atlanta, Ga., says: Celerina has always acted finely in all cases where I have tried it, especially in those troublesome cases of hysteria, nervous depression and feebleness, and prostration resulting from alcoholic excess. Have found its effects very exhilarating and nourishing. In fact it is my main dependence in all nervous diseases.

The psychological depressions and neuralgias, so common in the period following a debauch, are lessened or disappear altogether by the use of Celerina.

J. B. Johnson, M. D., 920 N St., Washington, D. C., says: I used Celerina not only as a nervine and tonic, but also found it most excellent, in two drachm doses, in sobering persons who were made drunk by alcoholic drink, and such patients informed me that they were greatly assisted in recovering from a spree by the use of Celerina.

After the removal of alcohol, Celerina, given in doses of from one-half to one ounce every four hours, is speedily followed by the most characteristic symptoms of improvement.

Dr. B——, Whitley, Northumberland, England, says: I have found Celerina valuable as a nerve stimulant and restorative in a patient suffering from the effects of a severe drinking bout.

RIO CHEMICAL CO., St. Louis, Mo., U.S.A.

THE ABOVE PREPARATION IS PREPARED EXCLUSIVELY FOR THE PRESCRIPTIONS OF MEDICAL MEN. A SAMPLE WILL BE SENT FREE TO ANY MEDICAL MAN WHO DESIRES TO TEST IT, ON APPLICATION TO

RIO CHEMICAL CO., 36, Basinghall Street, E.C.

THE LATEST DISCOVERY.

The Only Perfect Remedy for Dyspeptic Corpulency, Indigestion, and kindred affections.

May be freely used by the middle aged, and those inclined to stoutness.

Also of great value in Anæmia, and Ulcerous Conditions of the Stomach.

PRICE **2/-** *&* **3/9** *PER BOTTLE.*

"STANDARD BRAND" MALT EXTRACT is three times stronger in diastase than any other brand, and is much more economical, owing to its more concentrated form and smaller dosage. Remarkably beneficial in chest and digestive troubles. Also for weak and ricketty children.

PRICE **1/3, 2/3,** *&* **4/-** *PER BOTTLE.*

Samples sent post free to Medical Men, Qualified Nurses, and Chemists, on application.

MANUFACTURED BY THE

STANDARD MALT EXTRACT COMPANY, LTD., 21, WATER STREET, LIVERPOOL.

TRADE MARK.

DIETERICH'S
FERRO-MANGAN PREPARATIONS.

FERRO-MANGAN-PEPTONATE DIETERICH.
FERRO-MANGAN-SACCHARATE DIETERICH.
FERRO-MANGAN-IODO-PEPTONATE DIETERICH.

Ferro-Mangan-Iodo-Peptonate is highly recommended as a substitute for Cod-Liver Oil in the hot season. Very palatable, never refused even by children.

DIETERICH'S GLUE BANDAGES AND SOAP-GLUE BANDAGES
(PATENTED).

A handy and reliable substitute for Dr. UNNA'S Gelatines and for medicated soaps. No itching and irritation of the skin. Constant action of the medium with which they are impregnated. Great variety of composition.

GLUE BANDAGES with: Boric Acid, 3 per cent.; Ichthyol, 5 per cent.; Iodide of Potash, 2 per cent.; Iodoform, 5 per cent.; Sublimate, 0·1 per cent.; Mercury, 20 per cent.; Zinc., 25 per cent., &c.

SOAP-GLUE BANDAGES (Patented) with: Carbolic Acid, 5 per cent.; Ichthyol, 5 per cent.; Iodide of Potash, 2 per cent.; Sulphur, 10 per cent.; Tar and Sulphur, 5 per cent. of each, &c.

The Harveian Oration

ON

SCIENCE AND MODERN CIVILISATION.

Delivered before the Royal College of Physicians of London on Oct. 18th, 1897,

BY SIR WILLIAM ROBERTS, M.D. LOND., F.R.S.,
FELLOW OF THE COLLEGE.

I.

MR. PRESIDENT AND GENTLEMEN,—We have met to-day to commemorate a great name and a great discovery. By his demonstration of the true motions of the heart and blood Harvey laid the foundation of animal physiology as a department of exact science. This work is memorable, not only from its historical relation to physiology and practical medicine, but perhaps still more so from its constituting the earliest example of the solution of a biological problem of the first rank by an orderly process of observation and experiment, conceived and carried out on the lines of modern scientific research. Harvey flourished at the dawn of exact science. Indeed, he was himself one of the heralds of that dawn which in our own time has broadened out into such marvellous day. And I propose, on our present anniversary, to consider Harvey's life and work, not so much as they concern our special studies, but as symbolising the commencement of a new era in human progress—the era of exact science—which in the present age is slowly but surely transfiguring the aspects and prospects of civilised society. I need not long detain you over the particulars of Harvey's life. He was the eldest son of an opulent Kentish yeoman,[1] and was born at Folkestone in 1578. Harvey passed his schoolboy days at the King's Grammar School in the pleasant city of Canterbury. Thence he migrated, at the age of sixteen years, to Caius College, Cambridge. Harvey spent some three years at the University, and graduated as Bachelor of Arts in 1597, just three hundred years ago. At the age of twenty years he proceeded to Padua to pursue his medical studies. At that period Padua was one of the foremost universities in Europe, and was especially famous as a school of anatomy. Harvey passed four years at Padua, and had for teachers the most celebrated anatomists of the day—namely, Fabricius of Aqua Pendente and Casserius—names which are still embalmed in our anatomical nomenclature. It was obviously of the greatest advantage to Harvey in view of his future work that his attention was thus early fixed on the solid data of descriptive anatomy, which could be directly verified by eye and hand in the dissecting room, rather than on the pedantic aphorisms and cloudy speculations which constituted so large a part of the medical learning of that time. At the end of his course of study at Padua he obtained the degree of Doctor of Medicine, and returned to England in 1603. In the same year he received his doctor's degree from the University of Cambridge. The young Harvey now settled in London, and entered on his professional career amid the most favourable surroundings for commanding success, whether as a fashionable physician or as a scientific investigator. He was in easy circumstances, and he had the prestige attaching to the highest education the time afforded. In his twenty-sixth year he married a daughter of Dr. Lancelot Brown, who had been physician to Queen Elizabeth. This alliance must have brought him in touch with the nobility and Court circles. In addition, he was endowed with a brilliant intellect, a sound character, good health, and indomitable industry. To crown all, he was inspired with an enduring passion for original research—a passion which persisted throughout his long life of close on eighty years. With these manifold advantages, intrinsic and extrinsic, it is not surprising that Harvey made rapid way. At the age of twenty-nine years he became a Fellow of this College; at thirty-one years of age he was elected physician to St. Bartholomew's Hospital; and at thirty-seven years of age he was chosen Lumleian Lecturer on Anatomy to the College of Physicians. About the same time he was appointed physician extraordinary to James I. and subsequently physician in ordinary to his successor, Charles I. These latter appointments gave Harvey command of the herds of deer in the Royal parks for the purpose of the vivisections and dissections which he practised in the course of his researches on the motions of the heart and blood, and in his investigations on animal generation and embryology.

Harvey delivered his first course of Lumleian lectures in 1616, when he was thirty-eight years of age. It was in these lectures that he first propounded his views concerning the motions of the heart and blood, and demonstrated before the Fellows of the College the anatomical and experimental evidence on which he based his conclusions. These demonstrations were, as he tells us, annually repeated at the Lumleian lectures for nine or ten successive years, no doubt with ampler and ampler proof of the truth of the new doctrine of the circulation of the blood. It was only after this long and searching probation that Harvey ventured to give his discoveries to the world. This he did in the form of a little treatise printed at Frankfort in the year 1628. Before proceeding to analyse this remarkable work I will conclude what I have to say, and very briefly, concerning the other work and the rest of the life of Harvey. After the publication of his treatise on the circulation Harvey seems to have concentrated himself, as regards physiological work, on his investigations concerning the generation of animals. He bestowed long years and an immense amount of labour on this subject. Over and over again he minutely dissected the organs of generation in various kinds of animals. He watched with patient observation the slow growth of the embryo, from its earliest inception to its full maturity and birth. In this way he gradually accumulated an enormous mass of information which he embodied in fragmentary disquisitions, composed apparently at irregular intervals, as leisure and work permitted. These disquisitions were eventually collected together and printed towards the close of Harvey's life in a separate volume under the supervision of his friend, Sir George Ent, with the title of "Exercitationes de Generatione Animalium." This work, though many times larger than the treatise on the motions of the heart and blood, is incomparably less satisfying and conclusive. To the modern reader of these disquisitions the reason of their shortcomings is plain enough. Harvey was stopped—and stopped absolutely—at every critical point by his want of a larger magnifying power. He had at his disposal only a pocket lens, which magnified perhaps four diameters. The ovum must have appeared to him as a structureless mass of material, and the seminal discharge as a homogeneous fluid. He knew nothing, and could know nothing, of the cellular elements of the ovum, or of the motile filaments which constitute the "vital spark" of the spermatic fluid.

The later years of Harvey's life were passed in peaceful retirement. The civil troubles of the time had broken up his household and scattered his patients, but had left his private fortune unimpaired. At the age of sixty-eight years he relinquished his appointments and practice, and went to reside with one or other of his brothers, who were wealthy London merchants. He still continued the studies he loved so well, and maintained his interest in the College of Physicians. Sir George Ent gives us a touching glimpse of him as he appeared in his seventy-third year at the house of his brother Daniel at Combe. "I found him," says Sir George Ent, "with a cheerful and sprightly countenance, investigating, like Democritus, the nature of things. Asking if all were well with him, 'How can that be,' he replied, 'when the State is so agitated with storms and I myself am yet in the open sea? And, indeed, were not my mind solaced by my studies and the recollection of the observations I have formerly made, there is nothing which should make me desirous of a longer continuance. But thus employed this obscure life and vacation from public cares, which would disgust other minds, is the medicine of mine'" Harvey had the satisfaction of living to see his great discovery of the circulation of the blood generally accepted as true. In his old age he was known and honoured throughout the learned world. The College of Physicians erected a statue in his honour. In his seventy-sixth year he was

[1] In those days the yeomen of Kent were persons of consideration. There is an old rhyme which runs:—

A knight of Cales,
A squire of Wales,
And a laird of the North countree;
A yeoman of Kent
With his yearly rent
Will buy them up all three.

Digitized by Google

elected President of the College, but declined the honour on the plea of the infirmities of age. He accepted, however, the office of councillor, which he held for two years. He enriched the College with many gifts; he furnished the library with books, and filled the museum with "simples and rarities," as well as with specimens of instruments used in surgery and obstetrics. Finally, in the year preceding his death, Harvey made a transfer to the College of his paternal estate of Burmarsh, in Kent. In the deed of gift conveying this property to the College there is provision for a salary to the College librarian and for the endowment of this annual oration. The orator is directed to exhort the Fellows "to search out and study the secrets of nature by way of experiment, and also for the honour of the profession to continue mutual love and affection among themselves." This double injunction of our venerated saint and apostle has, I venture to believe, been fairly observed according to the measure of their abilities by successive generations of the Fellows of this College even to the present day. Harvey made a peaceful ending in his eightieth year, and was buried full of years and honour in his brother Eliab's vault in the parish church of Hempstead, near Saffron Walden, in Essex. Seventeen years ago, on Oct. 18th, 1883, by the piety of this College, his remains were removed from the dilapidated vault, and, with befitting solemnity reinterred in a marble sarcophagus in the Harvey Chapel attached to the same church.

Harvey's activity as an investigator ranged over a wide field, but his fame as a discoverer and his rank in the hierarchy of science must always depend on his researches on the motions of the heart and blood. These researches were published in 1628 in the form of a small Latin quarto of only seventy-six pages. This little volume embodies the results of some twenty years' work, carried on during Harvey's prime, when his inventiveness and receptivity were at their highest. The book is in several respects a remarkable one. It presents to us the earliest record we possess of a really scientific investigation in the domain of biology, based on observation and experiment. Although written 270 years ago, the work is essentially modern in tone and method. It is, in fact, the prototype of the scientific "paper" or "monograph" of our own day; and for clearness of demonstration and conclusiveness of proof stands favourable comparison with the most renowned masterpieces of recent times. Harvey begins with an account of the state of knowledge on his subject at the time he wrote. He describes the confusion and contradiction reigning in men's minds concerning the actions and offices of the heart and the movements of the blood. He then sets forth in a series of chapters the dissections, vivisections, observations, experiments, and reasoning by which he proved that the blood flows in a continuous stream along its now well-known route. He shows that the motor power for the movement of the blood resides in the heart, that the heart is a muscular organ, and that the auricles and ventricles are hollow muscles which contract in action and forcibly expel their contents. He demonstrates that the disposition of the valves within the heart, and at the roots of the aorta and pulmonary artery and along the veins, is such that the blood expelled by the contractions of the heart must of necessity flow onward in the direction indicated, and that any reflux in a contrary direction is a mechanical impossibility. He argues that the blood-stream must be continuous throughout its whole course, because, wherever you tap the channel, whether in an artery or in a vein, the whole of the blood contained in the body is drained away in a few minutes. He fortifies his argument by a number of collateral proofs, all converging and pointing to the same unavoidable conclusion. Especially ingenious and original is the following argument, which has a curiously modern ring about it. If you estimate the charge of blood delivered into the arteries at each stroke of the ventricle at one or two drachms, and calculate the rate at which the heart is beating at from 60 to 70 per minute, you arrive at a volume of blood passing through the heart in the course of every half-hour which is greater than the aggregate ingesta of a whole day, and greater than the total sum of blood contained in the body. The infererence is therefore irresistible that the whole of the blood, and the same blood, must be incessantly passing and revolving through the heart. Harvey was much exercised as to the precise way in which the blood found its way from the terminal arteries to the commencing veins. He had absolute proof before him that it did somehow find its way, but how? He was able, by minute dissection of the organs and tissues, to satisfy himself that it was not, as some of his contemporaries supposed, by coarse anastomosis between the arteries and veins. "I have myself," he tells us, "pursued this subject of the anastomosis with all the diligence I could command, and have given not a little both of time and labour to the inquiry; but I have never succeeded in tracing any connexion between arteries and veins by a direct anastomosis of their orifices. Neither in the liver, spleen, lungs, kidneys, nor any other viscus is such a thing as anastomosis to be seen; and by boiling I have rendered the whole parenchyma of these organs so friable that it could be shaken like dust from the fibres, or picked away with a needle, until I could trace the fibres of every subdivision and see every capillary filament distinctly."[2] Harvey with his simple lens could not detect the delicate capillary network which united the minute arteries and veins into a closed vascular system; and he was reduced to the conjecture that the blood percolated the organs and tissues as water percolates the earth and produces springs and rivulets. It is almost pathetic to contemplate this eager, earnest inquirer, looking with wistful, straining eyes for the communicating channel which he knew must exist, but could not see, and to remember that the solution of the puzzle was almost within his grasp; for hardly had he closed his eyes than the improvements in the microscope enabled Malpighi and Leeuenhoek to demonstrate the completion of the circuit of the blood through the capillaries in the web of the frog's foot. It is singular that Harvey in all his writings nowhere betrays any consciousness of his sore want of a higher magnifying power. He did not, apparently, divine that it was possible to enlarge objects beyond the power of the common lens which had been in use from antiquity, yet it was precisely this want which foiled him at almost every step in the prosecution of the studies to which he devoted his life.

When Harvey was entering on his career as an investigator, in the early years of the seventeenth century, the great movement of the Renaissance had produced its full effects. Starting in Italy in the fourteenth century, it spread during the fifteenth and sixteenth centuries and permeated the rising nationalities of Western Europe. It was through the zeal engendered by this movement that the priceless literary and artistic treasures of Greece and Rome were rescued from oblivion and made the secure heritage of all time. The study of those monuments of ancient genius and the inspiration communicated by them, saved mediæval Europe from barbarism and created a new civilisation not inferior in polish to that of the classical ages. Upon literature and the fine arts the spirit of the Renaissance reacted with the happiest possible effects. It inspired the masterpieces of poetry, painting, architecture, and sculpture, which constitute the glory of the fifteenth and sixteenth centuries, and compel the admiration and challenge the rivalry of the nineteenth century. But as regards natural knowledge the influence of the Renaissance was at the first, and even for a long time, distinctly unfavourable. The writings of Hippocrates, Aristotle, Ptolemy, Galen, and other masters were studied and searched, not for inspiration to new inquiry and higher development—but these great names were erected into sacrosanct authorities, beyond whose teaching it was vain, and even impious, to seek to penetrate. The result of this perversion was that the pursuit of natural knowledge degenerated into sterile disputations over the words of the masters. This numbing despotism of authority comatosed the intellect of Europe during many generations. It received the first rude shocks from the discoveries of the great anatomists of the sixteenth century; and it was finally overthrown by the force of the demonstrations of Galileo and Harvey—powerfully aided, no doubt, by the philosophical writings of Bacon and Descartes. These four men—Galileo, Harvey, Bacon, and Descartes—were the dominating spirits of their epoch in the sphere of natural knowledge; they were contemporaries; and three of them must have had more or less personal acquaintance with each other. Harvey was Bacon's friend and physician; and we can easily believe that much talk went on between the investigator and philosopher concerning the studies in which they were mutually interested, and that Bacon imbibed his enlightened notions respecting the importance of experiments in the pursuit of knowledge from the precepts and practice of Harvey. It does

[2] Works, p. 103.

Digitized by Google

not appear that Descartes was personally known to Harvey, but he was one of the earliest to accept the doctrine of the circulation and to write in its defence. When Harvey was a student at Padua Galileo occupied the chair of mathematics in that university. These two men take rank as the twin founders of modern science—the one in the domain of biology and the other in the domain of physics. Their lives largely overlapped; they were contemporaries for sixty-four years, and both nearly reached the patriarchal age of fourscore. Roughly speaking, their period of activity covered the first half of the seventeenth century. They were, each in his respective department, pioneers in the method of searching out the secrets of nature by observation and experiment, and in proclaiming the paramount necessity of relying on the evidence of the senses as against the dicta of authority.

II.

The present year is the 300th anniversary of Harvey's graduation at Cambridge and of the commencement of his career as a student and investigator of nature. That date (1597) corresponds roughly with the birth-time of modern science. The occasion is therefore not inappropriate for a survey of the changes impressed upon civilised society by science—after three centuries of expansion and growth. The lapse of time is sufficiently long and the advance made is sufficiently great to enable us to estimate approximately the scope and strength of this new factor in our environment, and perhaps even to appreciate the influence which the cultivation of science is likely to have on the future of modern civilisation. All the older civilisations have issued either in extinction or in permanent stagnation. The civilisations of Egypt and Chaldea and of Greece and Rome, after a phase of progressive decline, eventually perished by military conquest. The ancient civilisations of the Far East—those of India and China—still persist, and have a semblance of life, but it is a life of helpless torpor and immobility. Is our modern civilisation doomed to share a kindred fate? There are, I think, good reasons for believing that in this respect history will *not* repeat itself. Special features are observable, and special forces are at work, in contemporary civilisation which differentiate it profoundly from all its predecessors. It may be said, broadly, that the older civilisations rested essentially upon art and literature (including philosophy), and that modern civilisation rests in addition upon science and all that science brings in its train. This distinction is, I think, fundamental, and connotes a radical difference as regards stability and continuance between ancient and modern society. A comparison of the mode of growth of the fine arts and literature on the one hand, with the mode of growth of science and its dependent useful and industrial arts on the other, brings out this point very clearly. The evolution of literature and art displays the following well-marked characteristics. Starting from some rude beginnings, each branch of literature and each branch of the fine arts grows by a succession of improved ideals until a certain culminating level of excellence (or phase of maturity) is attained. When this level is reached no further growth takes place, nor even seems possible. When and after this summit level of excellence is achieved, all subsequent expansion, if any, is quantitative rather than qualitative, and consists in modifications, variations, repetitions, and imitations, but without any real advance in artistic and literary excellence. It may be further noted that there is observable in the past annals of literature and the fine arts a fatal tendency to a downward movement. The variations are apt to show meretricious qualities, which indicate, in the judgment of critics, a degradation from the high standard of the earlier masters. The life of each of the fine arts seems, as Professor Courthope has expressed it, to resemble the life of an individual in having periods of infancy, maturity, and decline. The witness of history bears out this view.

It is almost startling to consider how long ago it is since most branches of art and literature had already reached their highest known pitch of excellence. The Homeric poems are supposed to have been composed a thousand years before the Christian era, and no one doubts that as examples of epic poetry they still stand in the front rank. In the fourth and fifth centuries B.C. there occurred in Greece an extraordinary outburst of artistic and literary genius, such perhaps as the world has never seen before or since. During this epoch sculpture was represented by Phidias and Praxiteles, architecture by the builders of the Parthenon, painting by Apelles and Zeuxis, dramatic poetry by Sophocles, Euripides, and Aristophanes, and speculative philosophy by Plato and Aristotle. Greece maintained her political independence for two centuries after this period; but she did not produce anything superior or apparently even equal to the masterpieces of this golden age. A parallel sequence is observable in the history of ancient Rome. Art, literature, and philosophy, and all studies that may be grouped under these headings, attained their culmination in the Augustan age; and no advance thereupon took place, but rather a falling-off during the subsequent centuries of Imperial Rome's political existence. If we turn our eyes to the far east we see that the masterpieces of architecture and ornamental metal work and of poetic and philosophical literature are all old—many of them very old. Neither in India nor China nor in any other far eastern country are there any indications of advance for many centuries in the domain of artistic and literary culture. The history of Western Europe tells a similar tale. The finest examples of Gothic and Norman architecture date from the twelfth and thirteenth centuries. Painting culminated in Italy during the fifteenth and sixteenth centuries with Raphael, Da Vinci, Correggio, Titian, and Paul Veronese. The same art reached its highest level in the low countries with Rembrandt and Rubens, in Spain with Velasquez and Murillo, in France with Claude Lorraine and Poussin—all artists who flourished in the seventeenth century. In England nothing greater than the works of Reynolds, Gainsborough, and Turner have been produced by later artists. Similarly with literature: most of the masterpieces belong to a past age. Italy can show no higher examples of poetry than the creations of Dante, Petrarch, Tasso, and Ariosto. The most ardent admirers of the Victorian poets would scarcely contend that any of them stand on a higher pedestal than Shakespeare and Milton; nor would any German critic claim equality for any recent poet of the Fatherland with Goethe and Schiller. In the delightful art of music the masterpieces of Haydn, Handel, and Mozart, judging by their popularity at the present day, are not surpassed by the works of any of the later musical composers.

I need not pursue the subject in greater detail. Wherever we look—in all ages, among all peoples—we encounter the same story with regard to that large and varied and most precious outcome of the human mind which may be grouped under the categories of the fine arts and literature. There is a history of improvement and growth up to a certain culmination or phase of maturity. Beyond that point no further growth seems possible, but rather, instead, a tendency to decline and decadence.[3] The evolution of science differs fundamentally from that of literature and the fine arts. Science advances by a succession of discoveries. Each discovery constitutes a permanent addition to natural knowledge and furnishes a post of vantage for, and a suggestion to, further discoveries. This mode of advance has no assignable limits, for the phenomena of nature—the material upon which science works—are practically infinite in extent and complexity. Moreover, science creates while it investigates; it creates new chemical compounds, new conditions of substances, and strange new environments such as do not exist at all on the earth's surface in primitive nature. These "new natures," as Bacon would have called them, open out endless vistas of lines of future research. The prospects of the scientific inquirer are therefore bounded by no horizon; and no man can tell, or even in the least conjecture, what ultimate issues he may reach. The difference here indicated between the growth of art and literature and the growth of science is, of course, inherent in the subjects and is not difficult to explain. The creation of an artist, whether in art or literature, is the expression and embodiment of the artist's own mind, and remains always in some mystic fashion part and parcel of his personality. But a scientific discovery stands detached, and has only a historical relation to the investigator. The work of an artist is mainly subjective—the work of a scientific inquirer is mainly objective. When and after a branch of art has reached its period of maturity the pupil of a master

[3] If we take a wider view of the constituent elements of organised society, and embrace in our consideration the religious systems, the political and civil institutions, the military organisations, the commerce, and the miscellaneous disconnected mass of natural knowledge existing in the older civilisations, we look in vain for any constituent which had more than a limited scope of expansion and was not subject to decay.

Digitized by Google

in that art cannot start where his master ended and make advances upon his work; he is fortunate if at the end of his career he can reach his level. But the pupil of a scientific discoverer starts where his master left off, and even though of inferior capacity can build upon his foundations and pass beyond him. It would seem as if no real advance in art and literature were possible except on the assumption that there shall occur an enlargement of the artistic and literary faculty of the human mind. No such assumption is required to explain and render possible the continuous advance of science. The discoverer of to-day need not be more highly endowed than the discoverer of a hundred years ago, but he is able to reach further and higher because he stands on a more advanced and elevated platform built up by his predecessors.

III.

The fatal weakness of previous civilisations lay in the absence of any element which had inherent in it the potentiality of continuous growth and unlimited expansion, and this is precisely what exact science supplies to modern civilisation. A sharp distinction must be drawn between the so-called science of antiquity and the science of to-day. The ancients had a large acquaintance with the phenomena of nature and were the masters of many inventions. They knew how to extract the common metals from their ores, they made glass; they were skilled agriculturists; they could bake, brew, and make wine, manufacture butter and cheese, spin, weave, and dye cloth; they had marked the motions of the heavenly bodies and kept accurate record of time and seasons; they used the wheel, pulley, and lever, and knew a good deal of the natural history of plants and animals and of anatomy and practical medicine. This store of information had been slowly acquired in the course of ages, mostly through haphazard discovery and chance observation, and formed a body of knowledge of inestimable value for the necessities, conveniences, and embellishments of life. But it was not science in the modern sense of the word.[4] None of this knowledge was systematised and interpreted by coördinating principles or illuminated by generalisations which might serve as incentives and guides to further acquisitions. Such knowledge had no innate spring of growth; it could only increase, if at all, by casual additions, as a loose heap of stones might increase, and much of it was liable at any time to be swept away into oblivion by the flood of barbaric conquest. It is quite obvious, from the subsequent course of events, that there came into the world of natural knowledge about three centuries ago, in the time of Galileo and Harvey, a something—a movement, an impulse, a spirit—which was distinctly new—which Bacon, with prophetic insight, termed a "new birth of time." This remarkable movement did not originate with any startling revelation; it consisted rather in an altered mental attitude and a method. There arose a distrust in the dicta of authority and an increasing reliance on ascertained facts. These latter came to be regarded as the true and only data upon which natural knowledge could be securely founded and built up. Doubt and question took the place of false certainty. The hidden meaning of phenomena was sought out by observing them under artificially varied conditions or, to use the words of Harvey, "the secrets of nature were searched out and studied by way of experiment." *A priori* reasoning from mere assumptions, or from a few loosely observed facts fell into discredit. Observations were repeated and made more numerous and more exact. These were linked together with more rigid reasoning to stringent inductions. Hypotheses (or generalisations) were subjected to verification by experiment, and their validity was further tested by their efficacy in interpreting cognate problems and by their power to serve as guides to the acquisition of fresh knowledge. Instruments of precision were devised for more accurate observation of facts and phenomena—for weighing and measuring, for estimating degrees of temperature, the pressure of gases, the weight of the atmosphere, and for recording time. The sense of sight was aided by means of the telescope and microscope. The invention of instruments and appliances for assisting research was an essential and invaluable feature of the "new philosophy." It is singular that so little progress in this direction was made by the quick-witted Greeks of the classical period; and their neglect or incapacity in this respect largely accounts for their conspicuous failure in science as contrasted with their brilliant success in art and literature.[5]

IV.

The new method soon began to yield fruit—at first slowly, then more and more rapidly as the workers increased in number and the method was more fully understood. Discoveries were no longer solely stumbled on accidentally, but gathered in as the fruit of systematic observation and purposive research. It is not necessary for me, even if I had the time and ability, to trace the history of scientific discovery from the time of Harvey onward. I will only mention a few particulars by way of illustration. You all know how, as time passed on and knowledge expanded, the primary sciences became divided into separate departments for more minute study; how new sciences have arisen, some of which have now grown to vast proportions; show improved instruments and appliances of infinite delicacy have been invented to aid research; and how, in the present age, the gains of pure science have been turned to innumerable channels of practical utility. The advances made in physics and mechanics during the seventeenth and eighteenth centuries prepared the way for the invention and perfection of the steam-engine in the nineteenth century. The introduction of the steam-engine increased at a bound the power of the human arm many fold.[6] Through its instrumentality the land has been covered with railways and the sea with ocean steamers. Electrical science has given us the telegraph and telephone, a new illuminant, and a new motor. The steam printing-press, the telegraph, and the railway together, have made it possible to produce that perhaps most wonderful of all the indirect outcomes of the growth of science—the modern newspaper. The great science of chemistry has revealed the composition of the material world; has originated vast industries, which give work and wages to millions of the population; and has placed all kinds of manufacturing processes upon a basis of scientific precision. Under cover of chemistry have sprung up the sub-sciences of photography and spectroscopy, which have given a new and unexpected development to our knowledge of the heavenly bodies. The revelations of palæontology and embryology have led to the establishment on a firm basis of the theory of organic evolution. This theory—by far the most penetrating generalisation of our time—has not only thrown a flood of light upon the deepest problems of natural history, but has also revolutionised the whole domain of speculative thought. Physiology and practical medicine have profited immensely by the general advance of the sister sciences and by the adoption of scientific methods in the prosecution of research. Optical science gave birth to the achromatic microscope. The microscope has laid bare the minute structure of plants and animals and introduced zoologists and botanists to a vast sub-kingdom of minute forms of life previously undreamed of. The microscope, also, in conjunction with chemistry, founded the new science of bacteriology. Bacteriology has inspired the beneficent practice of antiseptic surgery; it has also discovered to us the parasitic nature of zymotic diseases, and opened out a

[4] "It is not a collection of miscellaneous, unconnected, unarranged knowledge that can be considered as constituting science."—WHEWELL.

[5] Whewell observes (History of the Inductive Sciences, vol. i., book 1, chap. iii.): "The Aristotelian physics cannot be considered as otherwise than a complete failure. It collected no general laws from facts; and consequently, when it tried to explain facts it had no principles which were of any avail." Whewell argues that this failure was not due to the neglect of facts. He goes on to say: "It may excite surprise to find that Aristotle and other ancient philosophers not only asserted in the most pointed manner that all our knowledge must begin from experience, but also stated in language much resembling the habitual phraseology of the most modern schools of philosophising, that particular facts must be *collected:* that from these general principles must be obtained by *induction;* and that these principles, when of the most general kind, are *axioms.*" Then he quotes passages in proof from Aristotle's writings. It is, however, pretty evident that Aristotle's reverence for facts was no more than a pious opinion, which he habitually ignored in the actual handling of questions of natural knowledge. His treatise "On the Parts of Animals" bristles with errors of observation which a very moderate amount of painstaking would have rectified. Had the ancient Greeks and their successors in the middle ages been more accurate observers of facts, and had they sought for and invented instruments for the more exact observation of facts, they would not have so conspicuously failed to establish at least the foundations of exact science. The historian of the inductive sciences, however, will have it otherwise. He sums up his argument thus: "The defect was that although they had in their possession facts and ideas, the ideas were not distinct and appropriate to the facts." Is it not rather the case that the "ideas were not distinct and appropriate to the facts," precisely because the "facts" were indistinctly seen and imperfectly apprehended?

[6] Mr. Mulhall calculates that "our steam-power in the United Kingdom is equal to the force of 169,000,000 able-bodied men—a number greater than the whole population of Europe could supply."—"National Progress during the Queen's Reign," p. 22.

fair prospect of ultimate deliverance from their ravages. Thus have the several sciences advanced, and are still advancing in concert step on step, by mutual help, at an ever-increasing speed—pushed on by that irrepressible forward impulse which has characterised the scientific movement from its inception. This movement has now become the dominant factor in civilisation.

There is no doubt that under the reign of science a striking amelioration in the state of society has taken place. The mass of the people are better housed and fed, and, above all, better educated. Their sanitary surroundings are improved and the death-rate has fallen. Crime and pauperism have diminished, and there is greater security for person and property. The amenities and enjoyments of life are on the increase, and the average scale of comfort is markedly raised. Moreover, this amendment is not confined to the material and physical well-being of the population. There is some evidence that the complex of conditions we term "modern civilisation" is acting favourably in the direction of making people more reasonable and better conducted. Peace is now the normal condition between civilised states; and there is a growing trend of opinion in favour of settling international differences by the more rational method of arbitration rather than by war. Political morality approximates more nearly to that recognised as proper in private life. The duel has almost been laughed out of court. Industrial quarrels are conducted with more order; there is an appeal to facts and reason on both sides, and more readiness to adjustment by compromise. The whole environment of modern life seems in several ways calculated to foster habits of correct thinking and acting. The inclusion of science in the scope of general education is a very important innovation. This extends the range of subjects in regard to which precise reasoning is possible; and tends to promote the application of scientific modes of thinking and reasoning to all the problems of life. We may be quite sure that exact thinking leads in the main to correct conduct; an evil deed is not only a crime, but also a blunder. The periodical press must, one would think, be a good training school for thinking and reasoning. The discussion of all sorts of questions in its columns can scarcely fail to have an educating effect. The disputants must perforce read one another's arguments and be, consciously or unconsciously, influenced thereby. It may be assumed, or at least hoped, that there is in arguments, as in organic forms, a tendency to the survival of the fittest, and that in the long run the better argument carries the day. The blaze of publicity amid which we live through the ubiquitous newspaper lends an additional motive to right-doing. The "fierce light which beats upon a throne" beats nowadays also upon the citizens, and doubtless helps to keep them in the straight path.

But, say the prophets of evil: "This will not endure; modern civilisation, based on science, will in time go the way of all its predecessors, and end in extinction or in decay and stagnation." It is proverbially unsafe to dogmatise about the future; and in all human affairs, even those termed scientific, there is nothing so certain as the unexpected. This, however, may be affirmed: that if modern civilisation is to come to an end it will not perish in the same way or from the same causes as previous civilisations. One of the standing perils of civilised communities in ancient times was the risk of being subjugated by less civilised neighbours or of being overwhelmed by hordes of barbarian invaders. This danger no longer threatens us. Power has passed for ever into the hands of the nations which cultivate science and invent. The appliances of war are now placed on a scientific basis; and the issue of battle is decided in the laboratories of the engineer and chemist. The late C. H. Pearson argued that the dark and yellow races, in virtue of their greater number and fecundity, might in time come to dispute the supremacy of the white races—that they would learn the drill and copy the armaments of European armies, and thus equipped would be able by their superior mass to hem in and curb, if not to subjugate, the western nations. But the march of science and invention never stops; and it is inconceivable that the scientific nations shall not always be many stages in advance of the unscientific nations in the destructiveness of their weapons and the perfection of their military equipments, and this would give them an advantage which scarcely any disparity of numbers could neutralise. The "yellow terror" can never be more than a phantom until these races begin to show capacity for scientific discovery and the further (and somewhat different) capacity for turning their discoveries to practical uses.

Against the more insidious peril of decay and stagnation the scientific movement seems also to offer effective safeguards. We sometimes hear complaints of the hurry and bustle—the stress and strain—of modern life; this unrest may incommode individuals—but it is the antiseptic of society. Probably the deadliest predisposing factor in the decline of former civilisations was the mental inanition arising from deficiency of fresh and varied intellectual pabulum. Physiological analogies lead us to the inference that an idle brain, like an idle muscle or an idle gland or nerve, would deteriorate in function; and, conversely, that a well-exercised brain would tend to reach its possible best. I conceive that our forefathers and the ancients, for the most part, led somewhat monotonous lives. They had but little fresh and varied food for thought. The generality could not, for lack of "news," take a sustained interest in the course of public events. The world of science was an unopened book. Intercommunication was slow and difficult, and the whole current of existence flowed sluggishly. Contrast this with the vivid abounding life of the present day. Veins of interest are greatly multiplied to meet and satisfy the infinitely varied individual aptitudes of men and women. A considerable number of persons of both sexes now busy themselves, either as amateurs or something more, with the study of some branch of science or natural history. Those whose bent is to politics, art, letters, sport, or fashion find in the daily newspaper and the periodical press an unfailing fresh supply of the mental food they love. Business and pleasure are carried on with a briskness formerly unknown, and the pulse of national life is quickened through every part. It seems impossible that decay should invade the body politic while such conditions of all-pervading activity prevail, and there is no valid reason why these conditions should not continue to prevail. It has often been remarked that periods of national upheaval, when men's minds are deeply stirred—like the rise of Islam, the Protestant Reformation, and the French Revolution—were exceptionally prolific of able men. It does not appear altogether unreasonable to suppose that the stir and movement of modern life may be similarly favourable to the production of "men of light and leading" for the service of the community. The proximate cause of the downfall of states seems always to have been a defective supply of strong and capable men at the head of affairs and in positions of trust. The *dolce far niente* is not conducive to the formation of strong characters, and those who sigh and yearn for social quietism may find comfort in the reflection that the hum and buzz which disturbs them is a sure token of the health and strength of the common hive.

Gentlemen, it is given to few to deliver a stroke of work like that of Harvey; but many of those before me have done something, and some a great deal, to forward the beneficent march of science. To lift the veil from even the smallest corner of the unknown in nature is not only a pure delight, but is surely also doing a service in the cause of humanity. We are here to-day all disciples of Harvey—paying willing homage to his great name; and though we cannot pretend to his genius we can all of us take to heart the lesson of his life and seek to emulate his gentleness, his patient industry, his single-minded devotion to a high purpose, and his unswerving loyalty to truth.

MIDLAND MEDICAL SOCIETY. — The annual meeting of this society was held in the Medical Institute, Birmingham, on Oct. 13th, the President (Dr. Alfred Carter) being in the chair. Mr. J. W. Taylor was unanimously elected President for the ensuing year. The report of the council and the treasurer's report were received and adopted. It was resolved to add £10 to the deposit account. Votes of thanks were passed to the retiring President (Dr. Carter), the treasurer (Mr. Garner), the retiring secretary (Mr. Heaton), and the auditors (Mr. Marsh and Mr. Haynes) for their valuable services during the past year. Mr. John Garner was re-elected treasurer, Dr. Kauffmann and Mr. Christopher Martin were appointed secretaries, and Mr. Marsh and Mr. Haynes auditors for the ensuing year. The following gentleman were elected to fill the vacancies on the council: Mr. Eales, Mr. Barling, Dr. Foxwell, Mr. Marsh, and Mr. Heaton. Mr. Greenwood and Mr. Wood were elected members of the society.

Address
ON
SOME RELATIONSHIPS OF INDIGESTION.

Being the First Hunterian Society's Lecture for the Session 1897-98, delivered on Oct. 13th, 1897,

BY W. H. ALLCHIN, M.D., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO THE WESTMINSTER HOSPITAL; EXAMINER IN MEDICINE IN THE UNIVERSITY OF LONDON.

GENTLEMEN,—In the living organism with its complexity of structure and intimate interaction of functional manifestations it is difficult, if not impossible, to conceive that when disease is established in one tissue or organ, however localised and however slight in degree, it can continue without producing some effect—some perversion both of structure and function in adjacent and associated parts. A morbid condition, in short, occurring in any region becomes thereby a disturbing factor in the environment of the surrounding area in which it tends to determine a secondary complication. The nature and severity of this latter will depend in great part upon the nature and extent of the primary disease as well as on the relationship, structural and functional, that may exist between the original seat of the mischief and the part secondarily involved. I have ventured to think that I might not unprofitably employ the hour that the courtesy of your committee has placed at my disposal in bringing before you some of the relationships which perversions of the digestive function bear to the organism as a whole, not only as regards the various precedent or causal conditions of such perversions, but also the disturbances which they in turn give rise to in parts remote from those primarily at fault. It appears to me that considerations such as these are essential to the proper understanding of the protean symptoms of dyspepsia, and for want of them, or of others similar, much confusion exists in the intelligent observance of the manifestations of indigestion and in their systematic investigation, as well as in formulating a rational and successful plan of treatment in place of the empirical and haphazard therapeutics which so largely prevail in this department of practical medicine.

The digestive organs, strictly speaking, are those concerned with the preparation of the ingesta, both solid and liquid, in such manner as may fit them for absorption into the blood current either directly or *viâ* the lymphatic channels. They consist of a canal many feet in length, suitably provided with means for the sub-division, mixing, and propulsion of the contents; and associated glands, some of which are in the thickness of the walls of the canal, others—as liver, pancreas, and salivary glands—at some distance from the tube, with which they communicate by ducts. Structurally the tract consists of a lining of mucous membrane, the epithelium of which presents the microscopic characters—spheroidal, columnar, and squamous—associated with glandular, absorbent, and merely protective functions. External to this membrane, in which the blood and lymph capillaries are disposed for the most part in a meshwork of adenoid tissue, is an arrangement of contractile muscular tissue so arranged as to effect the complex movements of mastication, deglutition, and gastro-intestinal peristalsis. The entire serous coat of the stomach and intestines takes no part that I am aware of in the digestive process proper. Genetically the epithelium of the canal with its associated glands, except that lining the cavity of the mouth, is derived from the hypoblast, whilst the connective tissue, muscular and serous coats with the bloodvessels and lymphatics are developed from the mesoblast, as the nerves are epiblastic in origin. The process of digestion—i.e., the reduction of the food to a diffusible state—is effected by the chemical agencies of certain acid and alkaline secretions, together with the ferment action of bodies whose nature is very imperfectly known, such as ptyalin, pepsin, trypsin; and supplementary to these changes, but as shown to be by no means essential to efficient digestion, are various disintegrations and decompositions brought about—at least in the intestinal contents—by the action of micro-organisms which have obtained entrance with the food and air that have been swallowed. Although carried out in different sections of the alimentary canal under the all-important influence of the body heat, the function of digestion is, to all intents so far as the actual body tissues are concerned, performed outside the body, and in respect to many articles of food is a continuation of the preliminary changes effected in the course of cooking. I have no need to enter into a detailed account of the specific action of the several digestive secretions which differ among themselves in the conditions needful for their activity, in the rapidity with which they produce their results, and in their relative importance to the efficient performance of the function. But there are several considerations of a general character upon which stress must be laid. It is all-important to remember that these secretions act upon the ingesta successively—that is, each one not only effects certain changes in one or more of the alimentary principles, rendering it more or less diffusible, but also determines other changes which are needful to the efficient action of the secretions which subsequently mingle with the food. Carried out in a progressive series of stages, each stage is marked by its own specific share in the process of digestion, and each contributes in some degree to the proper performance of those which follow. Disturbance of one, therefore, not only produces a direct effect, but indirectly affects those which come after.

A circumstance which confers a distinctive peculiarity upon the digestive function and characterises in no small degree its imperfection, is that there are special organs subject to the same kinds of structural disease as are other parts of the body, and there is also, to some extent independent of these organs, a material undergoing complex chemical changes. It is the existence of these two factors—organs and material—which has to be recognised in all questions connected with digestion, and to a certain degree to be considered separately as well as in combination. Comparison with the other nutritive functions shows nothing such as obtains in digestion. In respiration, e.g., noxious gases may be inhaled, but none are formed in the lungs; though poisonous bodies may be excreted by the kidneys they are not absorbed by those organs, and the same is probably true as regards the skin.

It is well with the purpose we have in view clearly to limit our conception of digestion to the conversion of the ingesta into a diffusible state. The further process by which the digesta are absorbed, intimately associated as it is with digestion proper on the one hand and with the circulation of the blood and lymph on the other, is nevertheless a different function and is carried out in its own peculiar way. And it is also desirable not to allow the nutritious character of the food taken to be confounded with its digestibility. The two qualities are not co-terminous. Many exceedingly nutritious—i.e., of value in the production of tissue or energy in the economy—substances require much digestion, whilst others demanding but a minimum of change to allow of their absorption may nevertheless be most harmful. How far in the course of the true digestive process the various aliments, in addition to those modifications in construction which render them diffusible, also enter on the path of those requisite alterations (anabolic or synthetic) which fit them ultimately for protoplasmic formation, having regard to the reconversion of some of the absorbed products to the form in which they were originally submitted to digestion, is a question that cannot be entered on here; but it would seem likely that some of these constructive changes do take place in the intestinal mucous membrane, and still more probably in the liver. Under healthy circumstances the successive stages of this complicated function are performed—except so far as the ingestion, mastication, and deglutition of the food and the evacuation of the egesta are concerned—without giving rise to any conscious sensation. But this state of health assumes a suitable dietary, a structural integrity of the organs concerned, an adequate vascular supply, and a normal nervous control. Improprieties or disturbances of one or other of these fundamental conditions determine imperfections in the digestive process, severe or slight, lasting or transient, and establish indigestion or dyspepsia.

In the whole category of terms used in the description of diseased states it may be safely affirmed that none are employed with less precision than are these synonyms. Scarcely two persons, lay or professional, attach to them the same meaning, and the conditions they are supposed to denote are the most diverse. This unfortunate vagueness of language commonly expresses a corresponding vagueness of idea, and a subject that is intrinsically difficult and uncertain is made more so by this lack of exactness in

Digitized by Google

language. It is difficult, no doubt, to be precise in the use of words the full significance of which is frequently changing with advances in knowledge or an altered point of view; but some attempt at consistency should be made and some common agreement arrived at which should prevent one authority applying the words to the failure in the digestive process restricted perhaps to one particular phase, and another of equal weight implying by them the symptoms which such failure may give rise to. Much of the difficulty would be removed by a preliminary definition of terms and a consistent use of them in the sense defined. I mean by indigestion or dyspepsia some perversion of the function of digestion, wherever in the alimentary canal, whether mouth, stomach, or intestines, this may take place, whatever may have been its cause, and whatever may be its symptoms. Though referring to perverted function I none the less conceive it as determined either immediately or remotely by some alteration in structure, be that alteration of a gross character or one requiring a microscope for its detection, or still further some abnormality in the "chemical structure" of the tissues concerned. Inasmuch as the first object of clinical investigation is to ascertain "what is wrong" and "how it is wrong" before attempting treatment, we regard the morbid signs and symptoms present in any case as the evidence upon which our opinion is based, and the more accurately we obtain the evidence the more correct is likely to be our final judgment. Clearly, then, the numerous and diverse symptoms which may result from a malperformance of the digestive function should be used as the material upon which the actual seat and nature of the fault should be diagnosed. To some minds so satisfying is the word "functional" that its application to a morbid state is considered to absolve the user from all further responsibility of seeking out the underlying causal and associated conditions, and a "symptomatic treatment" is the logical sequence. For the intelligent appreciation of the symptoms of indigestion, to refer them to their cause and rightly to interpret the bearings of the symptoms to one another, require, to my mind, these qualifications: a knowledge of the normal anatomy and physiology, an experience of the symptoms themselves and the circumstances under which they occur, and a systematic and orderly conception of the subject whereby the investigation of any given case may be pursued. As a contribution towards providing the last the following remarks are offered.

Given, then, some defect in digestion, there require to be examined, (*a*) the conditions which have given rise to it (the so-called causes), and (*b*) the perversions of well-being which it in turn has determined. The former is often far to seek and may at the best, with the present means at our command, be but imperfectly obtained, so complex are the circumstances; for the latter accurate observation is essential. Though regarded separately, it is none the less true that they are overlapping aspects of a common problem towards the solution of which each contributes.

The causal relationships of indigestion are of the widest; the antecedent conditions are well nigh innumerable, but they may be conveniently grouped thus—

A. Dietetic errors, improprieties in the ingesta.—These are among the most frequent, as they are the most obvious, causes of dyspepsia. It is not necessary that the food should of itself depart from a physiological standard; perfectly normal articles of diet may be presented under conditions which render them indigestible. Thus there may be far too much taken or a wholly insufficient quantity to excite the digestive process, the former error being, in this country at least, the more frequent. The excess or deficiency may extend to all the requisite alimentary principles or be confined to one of them; too much or too little fluid, for example, with meals may each be responsible for an impaired digestion. Or, again, certain ingredients may be so associated as to render them indigestible, whilst taken separately they are open to no objection; such, for instance, are starchy or proteid foods enveloped in fat, as met with in meat smothered in greasy sauces or hot buttered toast or pastry. Ices or iced beverages, perhaps harmless alone, may seriously interfere with the digestion of other substances taken with them. Or food may determine indigestion by being imperfectly cooked, by a too monotonous repetition or presentation in an unappetising form, thereby preventing rather than inducing the needful flow of saliva with such consequences as that brings about. Another and common cause of dyspepsia is irregularity in meals, upsetting thereby the rhythm of digestion, or, as when too quickly following one another, interfering with the gastric digestion in its progress. Nor must idiosyncrasy in respect to certain articles of diet easily digestible by the great majority be forgotten. These are possible circumstances in which suitable and fit food may become harmful. Not infrequently, however, the error consists in some element of the food being distinctly noxious. This condition is represented in its simplest form by articles of diet which contain a large proportion of material which is absolutely indigestible, for the digestion of which, that is, the solvent juices of the canal are incapable. Such are the husks, skins, and seeds of vegetable or fruits and many uncooked food stuffs. The ill effects of such bodies are mainly caused by the mechanical irritation they give rise to. More serious are the results which follow those ingesta which are more actively irritant or even toxic, such as mineral poisons or the more subtle agents developed in decomposing or tainted nitrogenous food. In estimating the results which follow one or other of these dietetic errors regard must be had to whether it be of occasional or habitual occurrence, and allowance has also to be made for the wonderful degree of tolerance which the human alimentary canal may acquire by habit.

B. Next to these immediate causes of an indigestion of external origin are those which arise in the body itself, and of these the simplest are: 1. *Imperfections in the performance of the various movements connected with digestion.* To insufficient mastication many a case of dyspepsia may be referred, and a habit of "bolting the food" is as frequently responsible for this as are defects in the teeth; whilst such causes as paralysis of the masticatory muscles or ankylosis of the temporo-maxillary joint are as obvious as they are exceptional. Disturbances of the normal peristalsis of the stomach and intestines however induced, whether by structural changes in the organs themselves or mal-innervation, are of common occurrence, sometimes accelerating the passage of the contents, at others delaying it, more especially perhaps in certain sections of the canal, but in any case interfering with the orderly and progressive sequence in the digestive stages which is so essential to the proper performance of the function. As regards the movements of the stomach proper there is reason to believe that they are capable of being aided in their effect upon the gastric contents by the movements of the diaphragm and even of the heart, which may together be sufficiently effective to compensate for the complete absence of the stomach peristalsis when that organ by adhesions or from other causes is incapable of acting. 2. Less obvious than these impairments of motility are the imperfections due to *faults in the composition and quantities of the digestive secretions*, although the growing practice of examining the stomach contents is doing something to provide more precise knowledge of this difficult subject. A deficiency of saliva, besides leading to failure in the amyloid digestion is indirectly harmful by removing one of the normal stimuli to gastric secretion, whilst an excess in salivary flow diminishes the activity of the changes in the stomach. An over secretion of hydrochloric acid or a considerable deficiency of the same is regarded as of more frequent occurrence than errors in the quantity of pepsin that may be found. But from whatever cause it may arise gastric indigestion not only determines its own particular perversion of the entire digestive process, but also tends to occasion disturbance further on by submitting to the other fluids a chyme which is ill adapted to be acted on by them. Of the precise effects of abnormalties in these later fluids—the bile, the pancreatic and intestinal juices—our knowledge is far from satisfactory, but we do know sufficient to be able to affirm that errors in their composition or quantity are followed by some fault in the normal intestinal changes. The problem to be solved is how to distinguish the indigestion primarily resulting from their shortcomings from that which is purely gastric in origin. 3. A third group of conditions liable to determine maldigestion are those brought about by *bacterial action in the gastro-intestinal contents.* In health the changes induced by these micro-organisms, which may be regarded as normal inhabitants of the canal, are accessory to and in some degree an aid to the regular chemical processes carried out by the secretions, although they are scarcely to be regarded as absolutely essential. But it may be easily seen that whether from the ingestion of toxic organisms or from the perverted action of those which are under ordinary circumstances harmless (such, for instance, as their having to deal with material of an unusual character) poisonous substances may be formed and indigestion set up. 4. Another source of

Digitized by Google

disturbance in the process of digestion is connected with a function of the alimentary mucous membrane and its glands, which is too often overlooked. It is forgotten that this membrane has besides its extensive secretory capacities a duty to discharge as a channel of *excretion*. Little is accurately known of this it is true, and it is probably when there is some general morbid state existing, such as fever, that this property of the mucous membrane is best appreciated. In this respect, as, indeed, in many others, the membrane may be compared with the skin, the eliminative powers of which even of products of intestinal fermentation are well known, as are also the results of their arrest. There is also good reason for believing that the accumulation of gases found in the stomach and intestine owe their origin in part to direct transfusion from the blood, especially when rapid distension takes place after the removal of ascitic fluid in hysteria and cardio-pulmonary disease. 5. Ordinarily the products of digestion as they become diffusible are absorbed from the stomach and still more from the small intestine into the blood and lymphatic currents, and not only the digesta but also the greater part of the many pints of the various secretions that are daily passed into the canal. It may not unreasonably be surmised that the gradual removal of these materials facilitates the necessary changes in that which still remains in the tube and that a failure in their absorption interferes with the normal course of digestion. In this way, then, such conditions as may *interfere with absorption*, a function quite distinct from that of digestion, may become the cause of a very considerable dyspepsia.

Having thus indicated *seriatim* the various directions from which digestion may be immediately interfered with, it must not be supposed that each acts alone, for seldom can such be the case. Far more frequently the causal or precedent conditions are a complex the factors of which interact in the production of each other as they also do in bringing about the diseased state. In order, however, to arrive at a more comprehensive conception of the causal relationships of indigestion it is desirable to consider these various groups of preceding and associated conditions from other points of view, such as how or by what means do they bring about their ill effects and to what more remote state or states may they in turn be referred. It is clear that, given one or other of these determining conditions of indigestion, it may act by irritation or injury of the structures concerned, that is the alimentary canal and its glands, leading to perverted action on their part; or its effect may be mainly, if not entirely, upon the material in the stomach or intestines which is undergoing digestion interfering therewith and having little or no effect upon the organs themselves; or it may be that the given cause acts in both of these directions. It is to the second of these, when the process is disturbed without any associated abnormality of the organs, that the term "functional dyspepsia" is alone permissible, if it be permissible at all. The ingesta, including therein the micro-organisms which gain entrance to the canal, are provocative of dyspepsia either by any direct unfavourable action they may exert upon the canal in virtue of irritant or toxic properties they may possess, and by setting up vascular, catarrhal, or even more serious inflammatory lesions lead to an impaired motility or perverted secretory action and thus determine an indigestion; or the same result may be reached by a direct interference by the ingesta, owing to its bulk or specific character, with the chemical processes carried on by normal secretions in a healthy canal, or the two modes of perverted action may combine in producing the morbid state. Disturbances of motility produce effects by prejudicially affecting the character of the digesting foodstuffs, interfering with their mechanical disintegration and the necessary admixture with the secretions, or by delay in propulsion favouring abnormal decompositions by the fluids or by organisms, a condition well exemplified in a dilated stomach or in a chronic constipation. It is to this cause also that sensory-motor symptoms such as colic are to be referred. Errors in the quantity or quality of one or more of the several digestive fluids, or perversions of the excretory function of the mucous membrane causing an escape into the canal of noxious bodies, or interference with the due absorption of the digested products, will act as causes of indigestion by disturbing the proper chemical changes in the canal, giving rise maybe to toxic substances which in turn react upon the mucous membrane and glands either directly or after absorption, thus establishing a vicious circle. Directly or indirectly, sooner or later, however apparently diverse the causes may be, the resultant is perversion of the chemical process to which, as will be seen, the manifold symptoms which may occur are to be referred.

Passing now to consider how these groups of causes may themselves beseverally induced, the ingesta may be at once dismissed and attention directed to those which arise within the body itself. Of these undoubtedly the most important are the errors in quantity or quality of the secretions. It has already been stated that our knowledge of this subject leaves much to be desired, and beyond the saliva and gastric juice we assume rather than know. But at least we can recognise two separate sorts of conditions which may determine such errors. The most obvious are primary structural defects in the organs concerned, whether these be of a temporary and transient character such as vascular states of congestion or hyperæmia and the milder inflammatory lesions, or those of a more permanent character, such as degenerations, fatty, lardaceous, and the like, or definite new growths; or such accidental complications as the blockage of the bile or pancreatic ducts by a calculus. The interference with the proper secretion of the various juices which such lesions may cause is apparent, and not less obvious is their harmful effect on the movements of the canal, on the excreting functions of the mucous membrane with its glands, and on the due absorption of the digested materials. It is going outside my present limits to discuss the etiology of these structural changes, though it must be remembered that some at least are induced by those dietetic errors which have already been referred to as causes of indigestion. More obscure, and perhaps on that account more interesting, are the morbid states of organs and functions apart from the digestive tract which give rise among other symptoms to some of a dyspeptic character. Foremost among these remote causes are those which may be classified as "nervous." Concerning the innervation of the gastro-intestinal musculature we have a certain knowledge both as to the share taken therein by the vagus and sympathetic respectively, and our information on the nervous supply and function of the salivary glands is as precise as any that we possess concerning secretion; beyond that much cannot be claimed. It would not be difficult, however, to adduce examples of indigestion which are clearly attributable to nervous states causing a disturbed peristalsis and a perverted secretion or both; the nausea, vomiting, diarrhœa, and even gastro intestinal pain which may result from violent emotional states are well known, and closely similar to such a centrally acting cause are those more numerous reflexly induced by such as ovarian and uterine diseases, renal or biliary calculus, &c. An excellent example of a dyspepsia of reflex origin is to be found in the indigestion so frequently accompanying phthisis quite apart from that due to an associated structural disease of the stomach and intestines. The explanation of the pathology of the condition we owe to the admirable work of Dr. Head,[1] who has shown that both during the very earliest stage before there are any marked signs in the lungs, and also during the stage of gradual invasion of the tuberculous disease, there are attacks of referred pain and superficial tenderness over the mid-dorsal areas, as well as bi-temporal headache and tenderness of the scalp. These sensory phenomena are liable to ensue "when the bases of the lungs become affected with disease of a certain type. But these areas from the sixth to the ninth dorsal stand in close relation with the stomach, especially those on the left side. These two organs, the bases of the lungs, and the stomach send sensory impulses into the same segment of the central nervous system; an affection of the one which causes referred pain and superficial tenderness tends to cause a reflex disturbance in the other organ that refers into the same areas." Hence the liability of symptoms referable to the gastro-intestinal tract when fresh outbursts in the lung have set up pain and tenderness in the areas mentioned. Such symptoms are nausea, loss of appetite, and even vomiting. "The tongue is at first quite unaltered, the bowels remain regular, and the evacuations are unchanged in character; the pain is not increased by food, and vomiting does not necessarily relieve the pain and headache. On the other hand, anything which relieves the pain and headache will remove the nausea and vomiting." The dyspepsia of the latest stages of phthisis, which "is rarely accompanied by referred pain and superficial tenderness, is mainly characterised by flatulence, eructations, and signs of dilatation of

[1] Brain, 1896.

Digitized by Google

the stomach and feeble motor and sensory activity, accompanied by marked signs of organic change in the walls and mucous membrane of the stomach." Whilst we may have some notion of how a peripheral nervous impulse may reflexly inhibit or stimulate gastro-intestinal peristalsis, we have no knowledge of the paths taken by such impulses as determine the secretion of a gastric juice deficient in hydrochloric acid or containing a large excess of that ingredient such as undoubtedly occurs, and with every reason to believe through perverted innervation. Whilst it is conceivable that the necessary fluids may fall short in their normal character from a deficiency of materials from which they may be formed by the secreting glands it is doubtful if such really occurs. But at the same time there are good grounds for believing that in conditions where the general tissue metabolism is gravely impaired or the chief excretory organs seriously diseased the consequent throwing into the circulation of unusual or excessive products of waste supplies to the several digestive glands a blood from which vitiated secretions are prepared. It is probable for various reasons that the liver is particularly liable to suffer in this direction. The frequent association of gastro-intestinal complication with renal disease is well known, and there is some reason to believe that the indigestion of this state is in part at least due to a perverted excretory function of the alimentary mucous membrane determined by the disturbance of the kidney function with its consequent failure to eliminate the waste products.

To summarise what has been said as to the causal relationships of indigestion, it would seem that the immediately preceding and associated conditions are separable into six groups, two of which are of origin external to the body, whilst the others are internal; and that the latter are directly referable to primary structural defects of the digestive organs or to impaired innervation of the muscular and secretory apparatus centrally or reflexly induced. And that whatever may be the nature of the disturbing cause it produces its effects almost entirely by interfering with the chemical processes which take place in the alimentary canal. It is this latter circumstance that confers upon digestive disorders their peculiarity, serving to distinguish them from the diseases of other systems and suggesting also the lines upon which their treatment, at least, in great part, should be based. It is less the disorders of the organs involved than abnormal processes taking place in the material undergoing digestion that constitute the *fons et origo* of most indigestions, and we have nothing like that to deal with when considering the morbid states of other functions, when for the most part some structural change, obvious or obscure, underlies the abnormal manifestations.

Having now considered the relationship which indigestion exhibits towards precedent and associated states, let us turn to those aspects of the subject which deal with the effects upon the organism which the indigestion itself brings about, with the sequential results of which it is the cause or antecedent, as exhibited by what are known as the signs and symptoms. The symptom complex which may attend any form of indigestion requires to be carefully unravelled ere the real relationships of the phenomena presented are satisfactorily understood and before a reasonable plan of treatment is formulated. To begin with there are the associated symptoms due, not primarily at least to the indigestion, but to the underlying cause of it and of them. Possibly no doubt the indigestion may tend to aggravate or modify these as they in turn may qualify the more strictly dyspeptic manifestations. Inasmuch also as the ultimate object of the digestive process is to supply the material for the tissue nutrition it may well be that among the remote results of an indigestion, especially if it be of any duration, the general nutrition should suffer. It is needful to differentiate the evidences of this from the dyspeptic symptoms proper. After making, however, due allowance for these there still remains a most extensive and varied range of departures from sound health of all degrees of severity which are distinctly to be ascribed to some flaw or other in the digestive process. The extreme diversity of these symptoms is one among other reasons which renders the investigation of the subject so difficult. But this very diversity is only what might reasonably be expected when the great extent of the organs is considered and the many and different phases of the digestive function is remembered. The widest and most abundant opportunity of disturbance exists in the natural condition of things, and the directions whence disturbance may arise being as numerous as they are a complicated and variable manifestation is the inevitable result. It will be convenient in the consideration of the symptoms and their bearings to adopt the distinction of *local* and *remote*, though it be in some respects an artificial arrangement and not capable of being strictly observed. By *local* symptoms is meant those which are obviously and directly connected with the digestive organs, and among the most constant are abnormal sensations. Inasmuch as the function should be performed without giving rise to any sensation after the food is swallowed it may be laid down that any conscious feeling in the course of the process is wrong. Frequently there is nothing beyond a sense of weight and oppression vaguely referred to the epigastrium or generally over the upper half of the abdomen, or this may amount to positive pain. Most variable and of uncertain significance is this symptom; strictly localised or widely diffused, relieved by pressure or acutely tender, stabbing, cutting and paroxysmal or continuous, are but some of the qualities by which it is marked. A nasty taste in the mouth with a furred tongue and foul breath may be the frequent complaint of one patient, whilst another, equally a dyspeptic, finds no place for such in his category of ailments. Acidity and heartburn, nausea and vomiting, uncomfortable distension of the abdomen, flatulence and the passage of wind, gaseous eructations and belchings of an acid or bitter or tasteless fluid, diarrhœa or constipation, with possibly an impaired appetite, capricious or entirely wanting, and unhealthy stools of all variety of consistency, odour, colour, and appearance, complete a list the items of which in all degrees and combinations constitute the local symptoms of indigestion.

It is not my present purpose to discuss these phenomena in detail nor to indicate so far as may be possible their respective significance as diagnostic of the nature and seat of the determining fault; but referring to the two main conditions under which, as we have seen, the various exciting causes of indigestion may be grouped—viz., obvious structural disease of the organs and direct interference with the chemical processes taking place in the stomach and intestines—it is certainly the case that these local symptoms are present in a greater or less degree whatever may be the character of the cause, and in the more pronounced and graver structural lesions they may almost be regarded as paramount, the remoter manifestations being in the greater number of cases scarcely existent. The symptoms immediately resulting from an indigestion not connected with the alimentary canal or its glands, but with parts and regions remote therefrom, are both clinically and pathologically the most interesting phenomena connected with dyspepsia. Insomuch as many of these are induced by affections of other systems they are not diagnostic of indigestion, and their true value in the diagnosis thereof becomes proportionately more uncertain, requiring more careful weighing for their proper appreciation. They may be the grounds upon which the patient seeks advice, and the manner in which they may be presented is often such as not to suggest, at least in the first instance, a digestive disturbance as being at the root of the matter. Since also they may and frequently do occur without any pronounced symptoms more obviously referable to the digestive organs the difficulty of diagnosis becomes the greater, and not seldom the condition may be regarded as one of primary nervous cardiac or pulmonary disease the relation to an underlying indigestion being so obscure.

Prominent among the *remote* manifestations are those which may be comprehensively designated "nervous," and of these headache is perhaps the most frequent in occurrence, as in turn indigestion is probably the commonest cause of headache. As regards locality, whether generally diffused or localised to the frontal, vertical, temporal, parietal, or occipital regions, the time of its occurrence in relation to food, its characters—so far as words can describe it—dull, aching, throbbing, &c., nothing specifically characteristic can be affirmed—nothing, that is to say, which can at once enable a given headache to be set down as dyspeptic in origin, however probable such may be the case. Once, however, its cause can be so defined some significance may be attached to these several features as helping to indicate the special factor or factors of digestion which may be at fault. But inasmuch as the laborious researches of Dr. Head have shown that these areas of pain with their associated areas of scalp tenderness are primarily at least to be regarded in connexion with corresponding regions of pain and tenderness over the trunk rather than with the thoracic and abdominal

Digitized by Google

viscera which may be at fault, the diagnostic value of headache in respect to dyspepsia becomes somewhat diminished. None the less, as symptoms of indigestion, headache, and hyperalgesia are amongst the most frequent, whilst the absence of tenderness, though the pain may be excruciating, distinguishes the true megrim from the bilious, sick, or dyspeptic headache. Scarcely less frequent than the foregoing, and often extremely distressing, are giddiness and vertigo. Subjective affections of sight, such as amblyopia, coloured flashes of light, muscæ volitantes, &c., or of hearing, such as tinnitus aurium, are also of no unusual occurrence in dyspepsia. The association of drowsiness with indigestion is generally familiar, but the connexion of wakefulness with the same state is not perhaps so well-known. The condition of irritability, of temper, contrasting so strongly as it does with the sense of comfort and placid well-being that attends a good digestion, is closely simulated in the course of still more remote disturbances of nutrition to which undoubtedly dyspepsia contributes to the development of, although it is here sought to distinguish between the symptoms for which indigestion is distinctly responsible from those due to the later metabolic change in the tissues which are really different from the true digestive processes. Attacks of mental depression amounting to actual hypochondriasis and melancholia with delusions of suspicion are well recognised as of frequent dependence on imperfections in digestion; the very name melancholia, a term of Hippocratic medicine, signifies the connexion. It has also been made clear that outbursts of mania or other psychic disturbances in those whose mental powers are perturbed are not infrequently traced to failures in the digestive process, especially if there be constipation. A close relationship between that condition of deficient nerve power known as neurasthenia and disorders of digestion has been described, although here again the general deterioration of nervous energy may more immediately be the expression of an impaired nutrition of which a dyspepsia may be but one factor in the production. Corresponding in some measure to neurasthenia of dyspeptic origin is a general sense of lassitude and muscular weakness of like cause, though partly due in all probability to an inadequate removal of the results of an abnormal tissue metabolism; and the same may be said for those violent cramps, more especially of the muscles of the calf, which not infrequently result from dietetic or digestive errors. Pains in the back and in the limbs, usually of a dull, aching character, the former sometimes due to a loaded colon, and therefore more properly to be reckoned among the local symptoms, are commonly complained of, or a pain about the right shoulder so frequently associated with hepatic trouble and to that extent a possible accompaniment of indigestion.

Among the disturbances of the circulatory function attributable to a disordered digestion may be mentioned palpitation and all degrees of cardiac irregularity up to complete intermittence or even fainting and pains over the region of the heart often closely simulating angina. The displacement of the organ by flatulent distension of the stomach or intestines may interfere with its action; but this is not the only way in which indigestion disturbs the heart. The effects exhibited by the peripheral circulation are not less marked, as witness the flushing of the face so often following a meal even free from alcohol and of the simplest character. The coldness of the extremities is another phenomenon of the same class. Respiratory defects are much less commonly observed, though the so-called "stomach cough" is among the symptoms appreciated by the laity. Whilst doubtless an expression of gastric or gastro-intestinal irritation, it does not usually accompany the more definite evidences of indigestion. A true dyspeptic dyspnœa is less well known, but of its existence there is little doubt both with other dyspeptic symptoms or so predominating as to obscure its real origin. Along with a sense of oppression and impeded breathing is a constant desire to take a deep inspiration occurring in attacks often of some hours' duration and not infrequently at night—a condition which recalls in its description an asthmatic paroxysm as provocative of which indigestion also takes a high place.

A connexion between indigestion and affections of the skin has long been recognised, although different opinions have been held as to the degree of the relationship. For whilst it is very certain that an eruption of urticarial wheals, of erythema, of pruritus, or even of eczema or acne rosacea, to mention only those cutaneous affections of most frequent occurrence, may follow the ingestion of certain articles of diet, just as these and other rashes may be caused by various drugs, the actual conditions of their development is apt to be most uncertain. Not only are such results met with in but few individuals and are of nothing like universal occurrence, but they are not constant even in the same individual, and they may or may not be accompanied by definite dyspeptic symptoms, such as pain, vomiting, diarrhœa, &c. Setting aside for the moment the question of how such eruptions are produced, it is doubtful whether they can be regarded as results of indigestion, and whether they are not rather to be considered as caused by the direct toxic action of certain ingredients contained in the articles of food with which the process of digestion is not strictly concerned. Sometimes there is good reason to believe that coincident with the cutaneous urticaria or eczema similar if not identical conditions are developed in the alimentary mucous membrane, and in such cases evidences of a perturbed digestion are of course likely to be manifested. The long-continued ingestion of certain articles of diet, such, for instance, as alcohol, may, by the injurious effect it exerts in the nutrition of the tissues, tend to produce certain skin affections, but such are not to be regarded as true dyspeptic phenomena, from which indeed they are really remote; rather are they true skin diseases predisposed to by the malnutrition which improper feeding or imperfect digestion have determined and immediately induced by some locally exciting cause. It is on the whole probable that the relationship of skin affections to dyspepsia is not so close as was formerly supposed, and that in most cases the element of idiosyncrasy has to be considered—a circumstance that would go far to shift the responsibility for any given eruption to the cutaneous structures themselves or their trophic governance rather than to place it upon a disordered digestion. The evidences of indigestion manifested in the urine are seldom the cause of actual discomfort to the patient, and beyond the familiar deposit of urates usually require an elaborate analysis for their detection, whilst as yet the significance of the abnormalities thus observed is only very vaguely understood. Even the precipitate of lithates, as well as of phosphates and oxalates, which may accompany very definite dyspeptic conditions are probably expressions of later metabolic perversions rather than of direct imperfections of digestion. It is very certain, however, that the process of digestion even in health does exercise a very real effect upon the character and composition of the urine as witness the increased alkalinity after meals and the variations in the amount of the nitrogenous constituents, urea, uric acid, and creatinine, with a full or diminished diet, although such bodies as these are only remotely connected with digestion and are products of tissue waste. The kidney as an excretory organ is concerned with the elimination of some of the results of intestinal putrefaction which are absorbed into the blood in place of being voided with the bowel evacuations. The most important of these substances are the aromatic sulphates and albumoses. The former are compounds of such bodies as indol and skatol with sulphuric or glycuronic acid and alkalies, especially potash. These bodies known as chromogens are themselves colourless though readily giving rise to pigments on the addition of acids. They are mainly, if not entirely, originally derived from the intestine, and their presence in excess may be regarded as an index of undue intestinal putrefaction. It has been proposed to ascertain the point at which excess is reached by considering the ratio of the ethereal to the so-called "preformed" sulphates or neutral salts of the alkalies, but the exact significance of their presence beyond the general fact I have mentioned I am unable to say. The existence of albumosuria or the very exceptional occurrence of peptonuria are indicative of a certain degree of proteid digestion, the products of which have been absorbed into the blood, and in virtue of their toxic properties have induced an irritation of the kidney and thus led to their excretion. But it by no means follows that this digestive process has taken place in the alimentary canal, for the albumins of the tissues may be so dealt with by microbic invasion. Even when their source may with reason be assumed to be the gastro-intestinal tract, their presence in the urine may not necessarily depend upon an error in digestion so much as some imperfection in the process of absorption from the mucous surface of the bowel. Glycosuria, oxaluria, and phosphaturia are probably but indirectly symptomatic of mal-digestion, whilst their relation to tissue metabolism is unquestioned. On the whole it may be said that the urinary abnormalities immediately due to dyspepsia are few, and interesting as they may be, and

Digitized by Google

valuable as is their promise, they cannot at present be said to count for much in the actual diagnosis of indigestion, far less to afford any indication of the precise nature of the digestive flaw.

In seeking to explain these exceedingly diverse and widespread results of an imperfect digestion it becomes necessary to consider the structural relations of the alimentary tract with the other organs of the body and thereby to trace the functional relationships which these remote symptoms express. By two distinct structures is this connexion established—the nervous and the vascular. The blood-supply to the alimentary organs is most extensive, so much so that at any moment a third of the total quantity of the blood of the body is contained in their vessels. This amount is easily capable of great increase by conditions of central or reflex origin which lead to paralysis of the splanchnic area. The direct arterial supply from the aorta possesses—at least, as far as the stomach and intestines are concerned—a most complete series of anastomoses sufficient to compensate for any arrest or obstruction to the circulation in any one part; and this direct supply *viâ* the cœliac axis and inferior mesenteric vessels is further supplemented by a most elaborate system of post-peritoneal communications between the visceral and parietal branches of the aorta sufficient, as has been shown, efficiently to carry on the circulation even when the main gastro-intestinal trunks have been obliterated. Even more extensive are the arrangements for the venous return, and although there is interposed an obstruction to the gastro-intestinal flow in the shape of the hepatic portal circulation, this is in part counteracted by the free communications between the gastric and mesenteric veins with the œsophageal and inferior hæmorrhoidal as well as the sub-peritoneal parietal venules. Accessory to this venous drainage, and also concerned in removing the digested products is the lymphatic system of vessels and glands. Our knowledge of the innervation of the digestive organs is in some particulars admittedly inexact. Fibres from both the cerebro-spinal and sympathetic systems are distributed to the various structures and in some cases have been traced to an intimate connexion with the muscular and glandular elements, but concerning the paths taken by many of the afferent impulses information is much to be desired. Enough is known, however, to enable us to recognise generally the connexion of the alimentary organs with the nerve centres and thus to appreciate the reflex and referred phenomena induced in other systems. So extensive and intimate a neuro-vascular connexion with other organs of the body at least indicates the possibility of remote symptoms being induced by digestive disturbances, suggests the channels by which they may be developed, and permits us to regard these disturbances as being in the nature of irritants to those distant parts, such irritation acting either on the nerve terminals in the digestive tract and so reflexly affecting the functional manifestations of other organs, or by the direct transference by the blood and lymph currents to these structures of toxic material absorbed from the gastro-intestinal canal. By whichever of these routes the remote organs become secondarily affected there appear to be two conceivable methods in which they may be disturbed—either by the direct interference with the normal activities of their protoplasmic elements, or by some modification of the blood-pressure in their vessels. That either of these methods is possible must, I think, be admitted, but proof of any one of them is at present wanting. But inasmuch as toxins are known to be formed in the alimentary canal under conditions of mal-digestion and the injection of bodies possessing poisonous properties into the blood current is well known to lead to the production of symptoms characteristic of the poison, it would seem highly probable, to say the least of it, that noxious substances absorbed from the intestine would equally determine morbid symptoms in distant parts. Doubtless to a very great extent the organism is protected against the enterogenetic poisons, and it may be—at least, in the majority of cases—that some impairment of the integrity of the intestinal mucous membrane is necessary to permit the absorption of the toxins, and this might be such as the poisons would themselves inflict on the epithelial cells. Whether when absorbed into the circulating medium these substances produce their effect directly on the tissues or indirectly upon them *viâ* the nervous system there is little or no evidence to show, merely surmise; but whether by either or both means such poisons would seem adequate to explain most if not all the remote symptoms which are properly referable to indigestion. That peripheral irritation of gastro-intestinal origin might of itself be sufficient to induce distal symptoms without the absorption of any harmful material appears possible, for the presence of intestinal worms has been known to produce such results. As to the other suggested explanation for some of the distal symptoms—viz., that they are due to variations in blood pressure reflexly induced by gastro-intestinal states—very little can be said. Such symptoms as giddiness, vertigo, and even some dyspeptic headaches, may be thus explained, and some grounds for this may be found in the circumstance that some of these phenomena may immediately disappear after action of the bowels—a circumstance that is always attended with a fall of blood-pressure as constipation is accompanied by the reverse. The relief from headache may follow so quickly as almost to negative the idea that the emptying the bowel has simply produced the effect by getting rid of toxic material.

Mention has already been made of the fact that definite structural lesions of the alimentary tract, however marked may be the local symptoms, are frequently wanting in any special evidences of perturbed function in other organs except in so far as they may share in the general malnutrition which the change engenders. Conversely it may be said that whilst disturbances in the chemical processes taking place in the stomach and intestines may, and usually do, give rise to local symptoms it is pre-eminently in connexion with these immediate digestive imperfections that the remoter manifestations are likely to occur and may indeed be the sole evidences. This distinction if true would be of distinct value for diagnostic purposes, and my experience leads me to believe it to be of some value in this direction.

Among the many features of dyspepsia that call for comment the uncertainty of its manifestations is as well known as it is remarkable. How commonly is it the case that a patient—the subject may be of frequent indigestion—consumes with impunity a meal that violates in quantity or quality most of the dietetic rules he has been accustomed to observe and has found almost essential to his well-being. What is one man's meat is another man's poison all are familiar with, and even how often the food which is suitable to-day may disagree to-morrow or the plainest fare may provoke an indigestion. The fact that what are called errors in diet do not of necessity induce discomfort, local or remote, and with many people rarely, if ever, lead to indigestion, would seem to suggest that the *materies morbi* is less in the ingesta as presented than in the subsequent digestion processes, and is to a great extent independent of the actual food taken. It is to remedy this that the treatment should be directed, and, as I fully believe, often with more success than by elaborate dietetic rules.

Lastly, if we compare the precedent with the sequential relations of dyspepsia, we find on the one hand the causal conditions acting in most cases by inducing a perversion in the chemical processes with production of toxins and themselves determined by noxious ingesta or by motori-secretory perversions due to structural change in the digestive organs or far more often to a defective innervation; on the other hand are resulting symptoms the expressions of local perversion of the digestive function or of the distant effects due to toxic absorption or reflex irritation.

My time, gentlemen, but not my subject, has reached its limits, and I am fully conscious that in the remarks I have made, or, perhaps, more particularly in the way I have treated my theme, that I have laid myself open to the charge of having expressed in too formal, too cut-and-dried a manner a subject which presents too much uncertainty and variety rightfully to admit of being so considered, and that I have aggravated my offence by saying nothing that is new. To the latter count I plead guilty at once, and can only urge in extenuation of the former that it is the want of some formal outline that appears to me to be responsible for some at least of the vagueness in which the subject is enveloped, and that what I have said, if it serve no other purpose, affords a basis for criticism and probable improvement. It is possible, of course, that my method tends to strain relationships and to overlook much that is important for the sake of uniformity, but, at the same time, it allows us to formulate what we do know and to indicate the directions in which we are ignorant, whilst I believe the suggestions I have offered to be more comprehensive than the groupings of dyspepsia which are commonly put forward. However lofty be the platform from which the superior mind unfettered by formality surveys the efforts of the systematic observer, there are many, I believe, who would be helped by some guide, imperfect though it be, in the labyrinth of morbid phenomena involved in "dyspepsia," and in that belief I have submitted

to your appreciation the foregoing remarks as embodying the considerations which, in my judgment, are essentially preliminary to the formation of a diagnosis, and, therefore, to the rational treatment of any case of indigestion.

WIDAL'S REACTION IN THE TROPICS.

BY W. C. BROWN, M.D. ABERD.

SINCE M. Widal in July of last year brought the reaction now generally associated with his name to the notice of the profession there has been in almost every issue of the medical journals some account of the theory, the technique, or the results of the test. But in view of the extreme importance of the subject and the fact that it has so far received but little practical attention in the tropics no apology is necessary for further increasing in some measure this amazing amount of literature. Nowhere is the correct diagnosis of enteric fever more essential than in the tropics. Nowhere is it more difficult, and nowhere has it been admittedly more unsuccessful. Opinions of the most careful and experienced physicians have been, and still are, hopelessly at variance as to the immunity and resistance of different races and individuals to the poison. The frequency of the occurrence of enteric fever, its power of assuming altered phases under altered climatic conditions, and its connexion with the ubiquitous malarial poison, are still undecided questions. It is held by many Indian physicians that natives of India are immune to enteric fever, and by others that it is their commonest scourge. In some text-books a variety of tropical fever is described as "typho-malarial fever." Lengthy descriptions are given of its symptoms, progress, and treatment. It is held by many of the best authorities that there is no such fever existing *per se;* that the cases described as typho-malarial are all referable either to the enteric or to the malarial type, and that if rarely a combination of the two occurs it must be regarded as a combination of two poisons and not as a separate and distinct disease. Post-mortem evidence has not availed to extricate us from this clinical confusion; almost, at times, it seems to increase the difficulties of differentiation. Fatal cases frequently occur which have exhibited a typical enteric temperature and well-marked abdominal symptoms, but which at the necropsy are found to be conspicuously devoid of enteric characteristics. On the other hand mild cases of what is apparently simple continued fever suddenly develop hæmorrhage from the bowel; severe cases of fever, with continued high temperature curve, constipation, and none of the usual symptoms of enteric fever, end fatally by perforation of the intestine, and a post-mortem examination reveals typical enteric lesions. And so far, and contrary to expectation, the microscope also has done little to help us. The frequency with which the malarial organism is met with in specimens of blood has no relation to the intensity of malarial infection. In the gravest cases of malarial fever examinations repeated at different times during a cycle of forty-eight hours frequently show an inexplicably normal condition of the blood. On the other hand, parasites occasionally swarm in the blood-stream of malarial patients who are able to walk about and are probably in better than average health. It is somewhat humiliating at this date to have to admit that a too implicit reliance on the indications for diagnosis afforded by the malarial parasite in any of its phases is a certain source of error; but so it is. Professional opinion in the tropics has in consequence become one of perpetual doubt. The physician, face to face with a grave fever, with the best aids to diagnosis at his disposal, has walked, if not in darkness, in the almost equally unsatisfactory twilight of uncertainty and doubt—an uncertainty incomprehensible to those who have not watched the rapidly changing phases of a tropical fever—a doubt which may not be dispelled even in the post-mortem room. In such a state of affairs the possibility of the existence of an agency that would reliably differentiate enteric fever has been eagerly canvassed, and the developments of sero-diagnosis have been watched and treated with unusual interest. There has now been sufficient time to form a just estimate of the help it will be likely to afford to tropical physicians; and after a somewhat extended investigation of the reaction I am of opinion that in the method of Widal we have been put in possession of a rapid and fairly easy test which, if not absolutely reliable, is of the very highest value. Clinical microscopical science must always be an inexact one; failures must occur in the application of this great discovery, but, if care is given to primary precautions, and attention paid to some simple rules, these can be reduced to a minimum.

Testimony as to the value of the reaction as a diagnostic test may at this date seem superfluous; it must, however, be of interest to know that in the tropics—probably the original *foyer* of all enteric fever—experience has shown that it loses none of its reliability. After a series of examinations of over a hundred suspected cases during the last five months I can point to only two instances where subsequent events did not confirm the diagnosis given by Widal's reaction; and in three cases that were not considered to be enteric fever the diagnosis obtained by means of the reaction received an almost startling confirmation in the subsequent history of the disease. I have appended a table of twenty selected cases from my case-book, showing the general character of the results obtained. Case 4 in the table is a striking instance of the diagnostic value of the reaction. My patient was a young Burman priest of good family who had been living for some time in a very malarial district. When I saw him after he had been brought here on the sixteenth day of his illness, he had had continuous high fever ranging from 103·5° to 104·8F., with no morning remissions; the bowels were constipated, there were no spots and no abdominal symptoms, and his condition was most critical. The case was considered to be one of continued malarial fever. The following day an examination of the blood was made. Malarial parasites in considerable numbers were found, but a slow reaction was obtained with a three days' culture of Eberth's bacillus on agar. The test was repeated on the next day with a 24 hours' culture, with the result that the reaction was somewhat more prompt and decisive. The patient appeared to improve rapidly until the twenty-first day, when he died somewhat suddenly from hæmorrhage from the bowel.

In the tropics a not uncommon form of malarial fever in Europeans may be described as "acute pernicious." It generally occurs in strong full-blooded individuals of middle age: fever comes on suddenly, runs up rapidly from 105° to 107°F. or higher, and is accompanied by marked head symptoms, delirium, and unconsciousness. Death, which invariably takes place within four or five days, is generally attributed to sunstroke; but if the brain is examined it is found to be highly congested and its capillaries blocked with malarial parasites. Case 6 was supposed to be a well defined instance of this grave type of malaria, but the blood gave a prompt and marked reaction with an eighteen-hour bouillon culture. Hæmorrhage from the bowel began on the sixth day, and death occurred from perforation on the 10th. No malarial organism was found, and the ileum was found to be extensively ulcerated.

So much has been written on the technique of the reaction that it appears necessary for me to deal with it only so far as it is influenced by altered climatic conditions. The tests have been confined to microscopical observation; naked-eye observation of serum in test tubes seems to require too much blood to be readily applicable to practice, and I have not been able to avail myself of the ingenious sero-sedimentation tubes of Professor Wright. In applying the test, otherwise a very easy process, the great difficulty—a difficulty which, I think, has been under-estimated but which is practically the only likely cause of error—is the difficulty of distinguishing between true and false clumps. If a loopful of blood serum from an enteric fever patient is mixed with nine loopfuls of a fresh bouillon culture or agar emulsion, the bacilli run together quickly in *true* clumps, the field clears rapidly between the clumps, and the bacilli become motionless. The clumps are characteristic in that they are closely packed, the bacilli actually seeming to *adhere* to each other in thick globular masses which are not all in focus at once. False clumps—the *pseudo amas* of French writers—are more loosely united; the masses are not so dense, and they are less globular. They can be brought into focus generally all at once, and the field is not so rapidly cleared of loose bacilli, for which the false clumps seem to have no specific attraction, and which retain their motility, though that also is lessened. How difficult the distinction is

Digitized by Google

we may gather from the conflicting opinions of bacteriologists on the characteristics of the grouped bacilli. Gruber has described a thickening of the enveloping membrane of the bacillus as distinctive of true clumping; but this alleged characteristic, though supported by several writers, is denied by M. Widal and M. Ricard.[1] If it exists at all, it is so insignificant as to be worthless as a diagnostic sign. Probably the best and only preventive against error is experience in comparison of false and true clumps. In the meantime the chief causes of the formation of false clumps should be noted in order that precautions may be taken against their occurrence. In my experience there are five principal causes of false clumping, and therefore sources of error, in the application of the test. 1. The dilution of the suspected serum may be too great or too small. This is a primary point insisted on by all observers and already fully described, and my own experience corroborates the view that a proportion of 1 part of serum to 9 parts of emulsion gives the best results, and that a stronger or weaker solution is apt to cause false clumping or failure of the test. 2. The culture may be too attenuated. There can be no doubt that if old cultures of the bacilli are used there is much more liability to false clumping. It is so difficult in the tropics to keep tubes of bouillon always ready for inoculation that if the test depended on the ideal condition of an eighteen hours' bouillon culture, it would be useless in practice. Fortunately it does not. The simpler the conditions of any test the greater its practical value. There is no difficulty about keeping cultures on agar, and the highest pitch of virulence and activity can be obtained by making use of a twenty-four hours' sub-culture from a twenty-four hours' culture. The more virulent the culture the more reliable the reaction and the less likelihood of false clumping. No rule, however, can be laid down; old cultures, though not reliable, and always to be used only as a *pis aller*, will often give a perfect reaction. It has been recently pointed out that dead bacilli possess marked agglutinative powers, and they will probably be the reagents of the future.

3. The mechanical preparation of the emulsion may be faulty. The best method to secure an approximately uniform strength of the emulsion is to place fourteen loopfuls of distilled water on a coverglass, to pick up as much fresh bacillus growth from the surface of the agar as can be easily seen on the end of a platinum needle, and to rub this down in the water until it takes on a faint, cloudy, homogeneous, white colour. Care should be taken to rub down the culture very gently but thoroughly. A twenty-four hour culture is easily rubbed down; an older one is more coherent. If the emulsion is not carefully prepared in this manner clumps of unseparated bacilli will be left floating about in the water. I have found a strength of one to fourteen the most suitable proportion for the emulsion, but the faint white colour it assumes is the best index of a right dilution. If it contains too many bacilli they are so crowded in the field as to obscure the reaction; if too free true clumping is more difficult to determine. All emulsions should be examined under the microscope before mixture with the suspected serum, for even in fresh bouillon cultures false clumps are not unfrequently seen. 4. The specific gravity of the emulsion may have altered since it was mixed. This is especially liable to occur in the tropics, and it is a fruitful source of false clumping and error. If the emulsion is allowed to remain on the cover-glass for a few minutes either before or after admixture of the suspected serum, altered physical conditions are established which favour the formation of false clumps. In order to avoid evaporation and drying which take place rapidly on a flat slide, it is best always to use the hanging drop method, and to moisten the edges of the hollow in the slide by water or a film of vaseline. Reactions on a flat slide are unreliable. After the emulsion is prepared it should be examined as quickly as possible, and never allowed to remain on the cover-glass without putting it on the slide. In working at this point I observed that if a hanging drop in which true clumping has occurred is allowed to dry almost entirely the clumps become fixed in position on the cover; but if the film is then rubbed up with a drop of water the clumps separate and the bacilli resume active movement for a minute or two. The agglutinative material then again

TABLE OF TWENTY SELECTED WIDAL'S REACTION TESTS.

No.	Sex.	Age.	Nationality.	Duration of illness.	Diagnosis (before test).	Reaction.	Remarks and diagnosis as established by progress of disease.
1	F.	18	Siamese	18 days	Enteric fever	Immediate	Death occurred on the twenty-fourth day from exhaustion and high temperature. No necropsy.
2	F.	54	Chinese	17 days	Continued malarial fever	Nil	Recovered. Plasmodia found in large numbers; no enteric symptoms.
3	M.	32	Chinese	33 hours	Malarial fever	Nil	No plasmodium found. Recovery was rapid under quinine.
4	M.	25	Burmese	16 days	Malarial fever	Slow reaction	Died on the twenty-first day from hæmorrhage of the bowel.
5	M.	30	Chinese	20 days	Beri-beri	Nil	Diagnosis was confirmed by necropsy.
6	F.	42	European	4 days	Enteric fever	Immediate	Death occurred on the eighth day from hæmorrhage of the bowel. Diagnosis was confirmed by necropsy.
7	M.	6	Eurasian	13 days	Enteric fever	No reaction	Recovery in ten days, with no confirmatory symptoms of enteric diagnosis.
8	F.	30	Jewess	13 days	Doubtful	No reaction	Apparently true enteric; duration of illness three and a half months; two relapses.
9	M.	36	European	15 days	Enteric fever	Immediate	A typical case of enteric fever masked by malarial symptoms.
10	F.	24	European	10 days	Enteric fever	Immediate	A typical case of mild enteric fever ending in recovery.
11	F.	18	Chinese	10 days	Enteric fever	Slow reaction	A severe case of enteric fever ending in recovery; plasmodia found.
12	M.	8	Eurasian	5 days	Congenital meningitis	No reaction	Test repeated on the twentieth day with the same result; death on the thirtieth day.
13	M.	2	European	5 days	Enteric fever	Slow reaction	Recovery in twenty-two days; a mild case of enteric fever.
14	F.	56	Chinese	16 days	Enteric fever	Immediate and marked	Repeated hæmorrhages from bowel; very severe case; recovery.
15	M.	29	Chinese	2 years	Leprosy	No reaction	No case appears to have yet been recorded of reaction of bacillus typhosus with leper's blood.
16	M.	24	Eurasian	10 days	Doubtful	Immediate	A severe case of true enteric fever; hæmorrhage from bowel; recovery.
17	M.	32	European	12 days	Enteric fever	Slow reaction	An ordinary case of enteric fever; recovery in twenty-five days.
18	M.	38	European	18 days	Malarial fever	No reaction	A doubtful case of continued malarial fever with some enteric symptoms. Plasmodia found.
19	M.	26	Hindoo	10 days	Enteric fever	Immediate	Recovery after severe hæmorrhage from bowel; no plasmodia.
20	F.	19	Chinese	21 days	Doubtful	No reaction	Probably malarial, but no plasmodia found.

Digitized by Google

exercises its power, and the bacilli clump once more. This would appear to indicate that true clumps are not so coherent as is supposed, and that the agglutinative action is paralysing and not killing. 5. The exposure to light may be excessive. It is laid down by most observers that clumping after a certain lapse of time is unreliable and a time limit of half an hour has been fixed by Gruber, Grünbaum, and others. This seems a reasonable limit if the specimen is removed from the microscope between each examination. I am of opinion, however, that this false clumping is caused by the strong rays of light from the condenser acting on the vitality of the bacilli, and if the specimen is kept on the stage all the time half an hour is too long. If, on the contrary, it is removed and examined once every five minutes for half an hour it is a reasonable time. If an emulsion without added serum is kept on the stage for half an hour clumps will occasionally be seen to form. Clumps that form after half an hour's exposure may therefore reasonably be considered quite unreliable.

Little need be said about the best method of collecting blood. Capillary glass tubes should be sterilised by heating them in a steriliser or an oven. Their ends should then be sealed. After washing the skin with alcohol the finger is pricked with a sterilised needle and the tube opened. The first drop of blood should be wiped off with the needle and the next drawn into the tube, which is then sealed. The specimen will in most cases be sterile, and may be kept for days. One or more cover-glass films of blood should be made at the same time for examination for malarial parasites. The serum will separate from the clot in the tube in about six hours and may be blown out on a slide practically free from corpuscles. The cases given in the table on p. 1037 have been selected principally with the view of illustrating the practical value of the reaction, and are a fair sample of general results in an examination of over 100 suspected cases. It will be seen that the diagnosis made before the test was applied has been recorded, as well as the evidence, confirmatory or otherwise, of its accuracy that was obtained by subsequent developments, and in some cases by post-mortem examinations. The view that enteric fever is very rare in adult natives of India has so lately as last August been endorsed by Surgeon-Major Freyer.[2] He explains this alleged exemption by a theory that natives gain a comparative degree of immunity in adult life from an almost universal and unsuspected prevalence of enteric fever in children. Whatever may be the state of affairs in India, I can only say that his theory is not supported by the results of blood examinations in the Straits Settlements, where the sanitary condition of Chinese and other races is little better than it is in India. Numerous control experiments have shown that if the necessary precautions are observed healthy blood serum, from whatever race it is obtained, has no agglutinative action on a fresh culture of the bacillus.

Penang.

ASSOCIATION OF REGISTERED MEDICAL WOMEN.—The opening meeting of the session of 1897–98 was held in the Library of the New Hospital for Women on Oct. 5th, at 8 P.M., Miss Cock, M.D. Brux., President, being in the chair. There was a large attendance of members, including some home on furlough from India and China. After some preliminary business had been transacted the following papers were read: 1. A Fatal Case of Meningitis, probably Tuberculous, Lasting Four Months, by Miss Anderson, M.D. Lond., of Manchester. (The paper was read in her absence by the secretary.) The patient was a child, aged three and a half years, and was not seen for a month after the beginning of the illness, so that no notes of the early symptoms were obtainable and no post-mortem examination was allowed. The diagnosis had therefore to be made from the clinical aspect of the case only and the significance of the various signs and symptoms observed was discussed. 2. A Visit to Aix-les-Bains, by Miss Helen Webb, M.B. Lond. Miss Webb gave a detailed account of the properties and uses of the waters at Aix-les-Bains, and dwelt specially on the excellence of the arrangements made in connexion with the administration of the baths and on the attention paid to the comfort of patients in many important respects. The paper was illustrated by photographs and charts prepared by Dr. Forestier, showing the changes produced in renal secretion by the different forms of treatment.

ON THE CONVEYANCE OF DIPHTHERITIC INFECTION BY APPARENTLY HEALTHY INDIVIDUALS.

BY ALEXANDER G. R. FOULERTON, F.R.C.S. ENG., D.P.H. CAMB.,
ASSISTANT BACTERIOLOGIST TO THE BRITISH INSTITUTE OF PREVENTIVE MEDICINE;
AND
A. LLEWELLYN WILLIAMS, M.R.C.S. ENG., L.R.C.P. EDIN.

THE following case is an excellent example of the conveyance of diphtheritic infection by an apparently healthy individual. It also furnishes an illustration of the importance under certain conditions of the bacteriological examination of the throat in those who have been exposed to the risk of diphtheritic infection, but have not themselves contracted the disease.

A pupil at a good preparatory school in the country, aged twelve years, was one amongst several boys who were attacked during February, 1896, with a form of tonsillitis, and in his case the symptoms appeared on the 13th of that month. On March 6th a "swab" taken from his throat was examined bacteriologically and reported on as being free from the diphtheria bacillus. The boy was shortly afterwards sent down to the seaside; he was suffering at the time from some difficulty in deglutition and from an attack of erythema nodosum, but the mucous membrane of his throat appeared to be quite healthy. He returned to school in May presumably well. During July of the same year a second outbreak similar to the former occurred at the school. The boy was not affected, but a swab from his throat was again examined and found to be free from the diphtheria bacillus. In the following November yet a third outbreak of the same nature occurred, and on the 30th of that month all the apparently healthy boys, the one under observation amongst them, were sent to their homes. During the three outbreaks there were altogether 43 cases, all amongst the boys, no one else being attacked. Two deaths occurred, both due to heart failure. On the school being broken up the boy did not return to his own home; as he had a younger and very delicate sister it was thought well to put him in quarantine elsewhere for a time. On Dec. 8th a swab taken from his throat was examined by one of us at the British Institute of Preventive Medicine and a pure culture of the Klebs-Löffler bacillus was obtained from it. This culture was of active virulence. A guinea-pig inoculated with it died in less than forty-eight hours. On the 13th a second swab was examined and the specific bacillus was again found. On the same date, his sister meanwhile having been sent away, the boy went to his home. Swabs subsequently examined on Dec. 15th and 20th, 1896, and Jan. 20th, 1887, were found to be free from the bacillus of diphtheria. On his return home the boy was more or less isolated from the rest of the household with the exception of a servant who alone attended on him. On Dec. 21st this maid showed obvious signs of an attack of diphtheria, and the Klebs-Löffler bacillus was cultivated from a swab taken from her throat on the same day. She was at once removed to a hospital, where she remained for six weeks. No other members of the household were attacked, and swabs taken from the throat of each of them proved to be free from the diphtheria bacillus. As regards the case of the maid no possible source of infection other than the obvious one could be suggested.

The Klebs-Löffler bacillus may be found in the throat of an apparently healthy individual under two sets of conditions. Of these the cases of more frequent occurrence are those in which the bacillus persists in and about the throat for a more or less lengthened period after complete convalescence from an attack of diphtheria. The other class of cases comprises those in which the bacillus exists in the throat of an individual, such as a nurse, who has been exposed to the risk of infection, but has escaped an actual attack of the disease. Cases which come within the first class are not by any means rare. But it is difficult to know the precise value to be attached to any figures bearing on the subject unless one at the same time knows the treatment which has been adopted in the various cases, since the persistence of the

Digitized by Google

bacillus is without doubt largely influenced by the method of local treatment adopted during the acute stage of the disease and afterwards. The most striking instance recorded is a French case in which the bacillus was still to be found in the throat at the end of fifteen months. But so prolonged an infection as this must be quite exceptional. Out of some 4000 bacteriological examinations in cases of diphtheria or of suspected diphtheria which have been carried out at the British Institute of Preventive Medicine, the case in which the longest duration of the bacillus has been noted is one in which it was found by Dr. Hewlett at intervals during twenty-two weeks. In this case, as in ours, the virulence of the culture was proved by experimental inoculation. Cases, again, in which the bacillus is still present three weeks or so after convalescence are in the experience of the Institute of not infrequent occurrence. With reference to this matter the following statistics lately issued by the New York Health Department may be quoted. They give the result of the bacteriological examination in 605 cases of diphtheria. In 304 cases the specific bacillus had disappeared within three days; in 176 cases it persisted for seven days; in 64 for twelve days; in 36 for fifteen days; in 12 for three weeks; in 4 for four weeks; in 4 for five weeks; and in 2 for nine weeks. The case above described, however, belongs, we think, to the second class; that is to say, we look upon it as a case in which the bacillus was found after exposure to the risk of infection in an individual who happened, whether because of a previous infection or not, to be for the time immune against the disease. That the bacillus had persisted in his throat for the forty-three weeks which elapsed between the commencement of the attack in February and the bacteriological examination in December is rendered improbable by the fact that two previous examinations in March and July had given negative results. During the three outbreaks at the school a very careful medical supervision was exercised over all the boys, and from the time when he left school on Nov. 30th up to the time when the bacillus disappeared from his throat a fortnight later the boy was under medical observation daily. It is therefore practically certain that he did not have a second slight attack of diphtheria in November, which might perhaps have otherwise passed unnoticed. As regards recent exposure to infection we ascertained that the boy was in the same class, but not in the same dormitory, as three of the boys who were attacked during the November outbreak. We are also informed that a bacteriological examination of the throat had been made in the case of several other boys from the school. In one case the diphtheria bacillus was found in the throat of a boy under very much the same conditions as those of the one under notice. Four other boys who had suffered from either tonsillitis or pronounced diphtheria in November were found to be still harbouring the Klebs-Löffler bacilli when their throats were examined between Jan. 20th and 30th. In three of these latter cases the bacilli were still present as late as the middle of February.

The treatment of such cases as these is usually satisfactory if thoroughly carried out. It is not sufficient to confine one's attention to the disinfection of the fauces and pharynx. The nasal fossæ also must be douched or sprayed with a germicidal lotion. The nasal fossæ appear to afford a habitat particularly favourable to the growth, or at any rate to the prolonged existence, of the bacilli. This view is supported by the results lately obtained by several bacteriologists who have shown that a bacillus identical both morphologically and in its pathogenic action on guinea-pigs with the Klebs-Löffler organism is to be found in certain cases of chronic rhinitis which had not hitherto been considered as of a diphtheritic nature. In those somewhat rare cases of prolonged diphtheria, too, in which after an acute onset a chronic membranous pharyngitis associated with the presence of the Klebs-Löffler bacillus persists, it may be for months, we believe that an affection of the nasal fossæ also has usually been present. In the case described the nasal fossæ were douched with a solution of sulphurous acid, with which the pharynx also was sprayed. This treatment was commenced on Dec. 10th, and five days later the bacilli had disappeared. A 1 in 2000 solution of mercuric perchloride will efficiently serve the same purpose, but must, of course, be used with a little discretion. This treatment has been recommended when advice has been sought at the British Institute of Preventive Medicine with regard to cases in which the bacilli have persisted in the throat after recovery from an attack of diphtheria, and in the cases in which it has been carried out and in which the results could be ascertained has been very successful.

The recognition of these cases is, it is scarcely necessary to say, of extreme importance from the public health point of view. They explain, for example, that recrudescence of diphtheria which is sometimes coincident with the re-opening of schools. They explain also the occurrence of a series of outbreaks with irregular intervals at schools, such as the instance we have more particularly referred to. And in passing it may be pointed out that it is such outbreaks as those mentioned which, in the absence of obvious evidence of the conveyance of infection from one patient to another, led in the past to the belief in the intimate causative relation between defective drainage and diphtheria—a belief now discarded because of the greater exactness in tracing causation which we owe to bacteriology. Medical men generally are now quite aware of the necessity for a bacteriological examination before a convalescent diphtheria patient can for the sake of others be safely released from isolation, however perfect the recovery may appear to be clinically. To this a further rule might with advantage be added: that after a school has been closed temporarily because of an outbreak of diphtheria no scholar should be re-admitted without a bacteriological examination of the throat, whether there is a previous history of diphtheria or not.

THOMSEN'S DISEASE: A FAMILY HISTORY.

BY J. C. CLEMESHA, M.D., M.R.C.S. ENG., L.R.C.P. LOND.

IN January, 1896, I was called to attend a man, aged thirty-three years, who was suffering from hæmoptysis. The symptoms and physical signs led to the diagnosis of phthisis. On inquiry into his past condition he mentioned being subject to a "family complaint," and I elicited the following history. At different intervals during the past twenty years he had been subject to attacks of transient paralysis, which generally affected his arms and legs, rendering him perfectly helpless. At times the muscles of the neck and head were included. He became affected about the age of thirteen years (puberty), and the other members of the family who were so affected were between the ages of thirteen and eighteen years when the disease first developed. Dampness and cold predispose to an attack—or, perhaps, to speak more correctly, are exciting causes. The attack begins by a peculiar sensation of clumsiness or uselessness in the hands and feet, which gradually increases until there is complete loss of power of motion. If, however, the patient, when he perceives these symptoms, walks for two or three hours he can abort the on-coming paralysis. Should he during one of these walks happen to fall he cannot get up without assistance, but when placed on his feet can go a long distance without fatigue. When the patient was younger these attacks came on every three or four weeks, but of late years three or four months may elapse between them and they are not nearly so severe. If an attack comes on during sleep, and he happens to have his arms and legs flexed, on awakening he is unable to extend them without assistance. In his father's case the muscles of the neck, head, and trunk have occasionally been involved in addition to the extremities, causing complete paralysis of the entire body.

The following information has been obtained from the patient's father, who stated that his mother had the disease and was the only one in a family of seven so afflicted. He was unable to state whether his mother's parents were affected. He had one brother, T—— (who had three children who were not affected), and one sister, M—— (who had no family), older than himself not affected. Two of his (the patient's father's) four children were affected. J——, the next brother, did not have it, nor any of his eight children. The next brother, J——, had it, and had a family of eight, only one of whom, the eldest son, had it. E——, a sister, had it when young, but seems to have grown out of it. She was not married. F——, a brother, had it, and died during an attack at the age of thirty-eight years. He was being carried downstairs when he "fainted" and died.

Digitized by Google

He was not married. V——, who never married, has not had it, nor D—— nor H——, nor their families. The disease in every case developed when the subjects of it were in their "teens." In the patient's father's case the attacks generally came on in the night, most frequently on Sunday night, the day's rest apparently predisposing to the attack. He had his first attack about the age of fifteen years. Cold and dampness seemed to have been exciting causes. He seldom had any premonition of an attack, but would wake up quite helpless and remain so for forty-eight hours, or if the attack was severe for three days. The head and neck were seldom affected. During the first attacks he had at times some difficulty in breathing. At first the attacks came on every year, generally in the spring, but of late only once in three or four years, but they were as severe as ever—even more so.

I was led to record the above family history from reading an epitomised account in a recent number of the *British Medical Journal* of an interesting and important article which was published in the *Deutsche Zeitschrift für Nervenheilkunde* by Dr. Goldflam. Five years ago he communicated some particulars of a family of eleven who suffered from occasional complete paralysis of all four extremities. He has since had the opportunity of carefully and continuously observing two of the members of the family. The condition affected the young people of the family, and showed itself in complete flaccid paralysis affecting the limbs and the trunk, and was characterised by loss or diminution of reflexes and of mechanical and electrical excitability of muscles. The muscles which were hypertrophied showed but little strength, and the examination of freshly excised portions showed that the fibres were unusually large, that the primitive bundles were wasted, and that there was vacuolation in them. In his first communication Dr. Goldflam hazarded the guess that the disease perhaps depended upon some toxic substance acting upon the muscles and their nerve-endings so as to influence and disturb them. This hypothesis receives a certain measure of support from the fact that a ptomaine-like substance is present in the urine of the patients and that a fairly constant condition of leucocytosis is also present. Possibly the poison exerts an influence on the muscles that have undergone some change in structure which renders them more susceptible to the influence of the substance. No doubt an analogy exists between such cases and those of Thomsen's disease.

Buffalo, N.Y., U.S.A.

SPRAINS OF THE JOINTS, WITH PARTICULAR REFERENCE TO SPRAINS OF THE ANKLE.

BY WILFRID B. WARDE, M.B., L.R.C.P. LOND., M.R.C.S. ENG.

DURING the past few years I have had unusual opportunities for studying severe sprains of joints, and more particularly of the ankle joint. At one time I had six cases of sprained ankle under my care in rapid succession. The observation of these and other cases and a contrast of various modes of treatment led me to certain conclusions which have had a most satisfactory result as far as my own practice is concerned.

If cooling lotions are used or if no special treatment be adopted a sprain passes through the following stages: (1) the joint swells and is very painful; (2) the pain and swelling during the next two or three days are increased by inflammation; (3) usually the joint is distended with synovial fluid; (4) the swelling slowly disappears; (5) considerable stiffness is felt which is slow in disappearing; and (6) there is great tendency to relapse. To one who has tried this kind of treatment and then tried the effects of pressure the contrast is most marked. Pressure, to act most efficiently, must be uniform and should be applied as early as possible in order to check the flow of blood from the injured vessels, which appears to be the cause of the early swelling of the joint. There is nothing better for the purpose than the starched bandage with a good thick layer of wool to completely envelop the joint. The effect of such treatment is as startling as it is satisfactory. The pain is immediately lessened, the swelling is arrested, the subsequent improvement is far more rapid, and there is less tendency to relapse. Uniform pressure acts mainly by lessening extravasation, and certainly the other results follow.

But pressure acts in another way. The more swelling there is the greater will be the interference with all movements of the joint, and, further, the greater the distension and the longer it continues the more relaxed will be the tissues, and so there will be a greater tendency to relapses. If pressure has been well applied from the beginning it is astonishing how little real stiffness, as opposed to mere weakness, there is, and it is quite easy to keep the joint from becoming distended when the patient begins to walk about. Some, however, appear to carry the principle of pressure a little too far. The injured joint is put up in plaster-of-Paris and kept in its casing for several weeks or even two or three months. This is going to the opposite extreme. The joint when set free is very stiff and often exceedingly weak.

I cannot do better than briefly describe the course I have adopted of late in severe sprains of the ankle. As soon as possible I cover the joint with a stiff starched bandage over a thick covering of wool. The limb is kept raised and at rest. At the end of a week I slit up the bandage, examine the joint, and move it as far as it will go in all its movements. It is no uncommon thing then to find that almost all swelling has disappeared and that the movements are fairly good. If the injury is very severe I place the joint back in the original covering, apply over it a fresh bandage, and have that starched. This at the end of another week is again slit up and the joint moved about freely. In slighter cases I re-apply the old cover and simply put a bandage over it. This is undone every day and the joint well worked. When from ten to fourteen days have elapsed from the date of the injury I allow the patient to begin to walk, and the distance covered is increased every day. After three weeks I make the patient use a well-known orthopædic exercise which consists of alternate flexion and extension of the ankle joint with rotation of the foot. It is no uncommon thing to have such a case practically well in a month and absolutely free from stiffness and weakness in six weeks. There is no tendency to relapse. For a severe sprain of the ankle such a result is satisfactory.

Knowsley.

ISOLATION IN SCARLET FEVER UNNECESSARY AND INEXPEDIENT.[1]

BY ARTHUR WIGLESWORTH, L.R.C.P. LOND., M.R.C.S. ENG., L.S.A.

I HAVE on several occasions called your attention to the great value of carbolic acid in the treatment of scarlet fever, for in my hands it has proved a specific for that hitherto much dreaded zymotic disease. Without troubling you again with details I may summarise the results by stating that if I saw my patients in the *initial* stage of the disease they all recovered; that I have had only three cases of albuminuria, all transient in duration; only one of glandular suppuration; and all other usual sequelæ have been characteristically absent. Finally, all the patients have recovered in a remarkably short space of time and with but little enfeeblement of strength. This treatment consists in administering to all patients, so soon as scarlet fever is suspected or diagnosed, from one to six grains of carbolic acid (according to age) freely diluted with water and continuing it every two hours until the rash has finally disappeared, and then reducing the dose and frequency of administration until convalescence has been fully established. This practice I have pursued for over sixteen years and each succeeding year confirms my opinion of its inestimable value.

The subject of this paper has, however, only recently forced itself upon my attention, and was chiefly due to a perusal of Flügge's work on Micro-organisms, which has given me a scientific basis to work upon. It is to this scientific

[1] The above paper was read before the Liverpool Medical Society nearly four years ago. Subsequent experience has amply confirmed these views so far as practical observation can demonstrate their truth. Considering the rapid multiplication of bacteria, as stated by Cohn, it is imperative that the administration of the acid should commence immediately on the outset of symptoms leading even to a suspicion of scarlet fever. The complete success of the treatment will depend on a strict observance of this rule.—A. W.

Digitized by Google

basis, founded upon pathological experiments, as described in that work, that I desire to call attention. I may premise that it was not till some years after I commenced the use of carbolic acid that I was led to adopt my present views and prepared for this latest development. The first stage was to administer carbolic acid as a possible prophylactic; and it arose in this way. Two children in a family were attacked with scarlet fever, and it was found quite impossible to isolate them from the rest of the children—three in number—because there were only an elder sister and the mother to attend to the wants of the entire household. I put this sister and the other two upon two-grain doses of carbolic acid administered twice a day, and the freest communication existed between the inmates of the sick chamber and the rest of the household. The result was eminently satisfactory; none of the rest took the infection, though about three years afterwards they were attacked, showing that there was a susceptibility to the zymotic poison.

With the experience thus gained I decided to pursue this line of prophylactic treatment in all subsequent cases, giving carbolic acid to those not infected, and then allowing the freest communication between the attendants in the sick room and the other inmates of the household; but not allowing uninfected children to enter the sick chamber. The results of this treatment were remarkably striking. I found that most of the household escaped infection altogether, but they not infrequently had an attack in after years. That those who did take scarlet fever invariably—there is not a single exception—took the infection in a milder form, and in only one instance did a sequela occur; finally, that after disinfection no other cases ever arose unless imported from a fresh source. I concluded, therefore, that there was some special effect produced upon the unknown micro-organism of scarlet fever which rendered it much less virulent, and this view seemed to me to receive a measure of support from the fact that whenever a patient had taken a certain quantity of carbolic acid a peculiarly dark colour of the urine appeared (which I now look upon as indicative of "carbolisation" having been effected), and that when this was produced the urine would remain free from the usual putrefactive changes from a week to a month, and if it occurred ultimately the usually highly offensive ammoniacal odour of putrid urine was almost absent. It was not, however, until I had read Flügge's work that many points which I did not understand were made clear to my mind, and thenceforward I entered upon a new course—namely, *that of abandoning isolation*—hitherto with highly successful results. My plan, therefore, is to first carbolise my patient with doses according to age, and at the same time to put all the uninfected members of the household on carbolic acid, and when the characteristic hue has become manifested in the urine of the patient to introduce into the sick chamber the other children, allowing them free access to the invalid until desquamation is completed and the house disinfected. Before, however, giving details of cases in support of this unusual procedure I must give the following few extracts from Flügge's work concerning bacterial attenuation, which determined me to pursue my present course. "The loss of the fermentative or pathogenic properties (in micro-organisms) is shortly termed the '*attenuation of the bacterium.*'" "The vital phenomena which are in this way lost (as far as has yet been ascertained) are only the power of producing fermentation and that of exciting disease." "The smallest degree of injury which micro-organisms can experience as a result of external influences consists in the disturbance of their complete development." "Minute departures from the normal conditions of existence often lead to a cessation of some one biological function. Thus by alterations ..... we may have cessation of the swarming power, of the secretion of peptonising ferments, of the fermentative action, &c.. whilst growth multiplication and all other vital phenomena remain unaltered." "Their power in producing disease also may be influenced by similar trivial alterations in the conditions of life, and may be even temporarily removed ..... for example, by *small doses of specific poisons* we might be able to neutralise the superiority of the pathogenic bacteria over the cells of the animal body." "By noxious influences of definite intensity we may so alter many bacteria that they lose certain of their vital functions." "The noxious factors which are suitable for this action are less energetic than those which cause complete death of the bacteria; on the other hand, the effects are more marked than in the case of inhibitory means, which only exert their influence so long as they are present in the nutrient substratum." "At times, however, the greater effect necessary for *attenuation* can be produced by sufficiently long-continued action of the milder means." "When properly regulated, various chemical poisons are able to produce a permanent attenuation." Pasteur, writing on "The Attenuation of Bacteria" by chemical means, says: "*Each cultivation* of the attenuated bacterium is a *vaccine* for the more virulent—that is to say, a virus capable of producing a more benign malady." "The bacteria attenuated by antiseptics, whether they give rise to spores or not, preserved their *diminished virulence* through repeated cultivations" "It would seem, therefore, that the new (or attenuated) virulence of the varieties of bacteria thus produced is the better fixed the more gently the modifying influence acts upon them." These, then, are general principles concerning the attenuation by chemical agents of those bacteria which cause disease.

The next point to which I would briefly direct attention is an important one to the subject in hand—viz., the action of carbolic acid as an "attenuator" and "bactericide" upon a given bacillus. The anthrax bacillus, observes Pasteur, has been experimented upon more than any other—the one best studied. It is one comparatively easy of cultivation, has marked and distinctive characters, and is one of the *most resistant* of the bacillus tribe to inhibitory influences, and being a facultative parasite affords every facility for experimental observations; hence its behaviour under the influence of carbolic acid is of very great importance, because this acid alone of all the more powerful germicides is one that can be given in large and repeated doses, and these can be continued for a lengthened period of time without producing any deleterious effects upon the system or its organs, unlike many of the mineral and organic germicides. In all the experiments made on the anthrax bacillus it should be borne in mind that its cultivation was made in the most nutritive fluids—i.e., those that were the most favourable for the growth, multiplication, and development of its virulent powers—and that the varying proportions of the carbolic acid were added to these fluids. Therefore, the bacillus had advantages conceded to it which were foreign to its habitat in the animal body, whilst conversely a certain but unknown percentage of *disadvantage* accrued to the germicidal powers of the carbolic acid, because when this special form of nutrient material is withdrawn the carbolic acid acts with far greater energy. There is a considerable difference, however, exercised on those anthrax bacilli which have spores and those free therefrom. Bacteria free from spores are completely and rapidly destroyed (not attenuated merely) by a very small proportion of carbolic acid, being killed in a few minutes when from 0·25 to 0·5 per cent. is added to the nutrient fluid, whilst from a 4 to 5 per cent. is required to destroy its spores in from twenty-four to forty-eight hours. Gärtner and Plagge, however, found that a 3 per cent. solution was required to destroy the non-spore-bearing anthrax bacillus, but that this was accomplished in eight seconds, and a 1 per cent. solution caused their rapid disinfection. All experimenters, however, agree that carbolic acid is a very efficient bactericide.

The next series of experimental results to which I would direct attention is the *amount* of carbolic acid necessary to attenuate this very resisting bacillus. Koch found that there was a distinct hindering of growth when $\frac{1}{1250}$ of acid was added to the nutrient fluid, and that a complete cessation of growth occurred when the strength was increased to $\frac{1}{850}$. In these experiments it was found that the "action of the antiseptic was to diminish the virulence of the bacterium," and by continuing these experiments, by cultivations taken at lengthening intervals from the original flask containing the antiseptic, it was found that decreasing virulence was exhibited until an attenuated virus was produced capable of preserving animals from a fatal form of anthrax—i.e., a *vaccine* was the resultant. All these experiments were made outside the body, and under the most favourable circumstances for the growth and strength of the bacillus, but a great difference was observable when it was taken direct from the blood and then exposed to the action of the antiseptic. For instance, Koch observes that bacterial filaments taken from a virulent drop of blood in a case of anthrax soon perished when placed in a solution of carbolic acid of $\frac{1}{600}$, though, if a similar drop was put into the nutrient broth and carbolic acid of the same strength was added, the bacilli lived and grew therein. Lord

Lister, in his observations, has found that normal blood serum is by no means a favourable soil for bacterial growth, and he states that he has returned to the use of carbolic acid for disinfecting purposes. So much, then, for the definite and decisive experiments with carbolic acid on the anthrax bacillus, but in drawing comparative reasoning between its action on this bacterium and its supposed action on that which causes scarlet fever we at once pass from the domain of fact into the region of theory. Nevertheless, I think it may be taken for granted that the same general laws which govern the attenuation and ultimate destruction of the known bacteria, though outside the body, will also govern, in a measure, these effects in the unknown ones, especially if their usual zymotic effects in a certain measure correspond. Nevertheless one naturally feels at a grave disadvantage from the fact that a scarlet fever bacterium has never been discovered. Still, I think no one doubts in these days its absolute existence, and that it partakes naturally of a virulent character, often modified, however, by a variety of unexplained circumstances.

Bearing in mind the potent action of carbolic acid on anthrax bacilli outside the body I was anxious to discover what amount would have to be given to a patient suffering from anthrax provided the effects were similar, with a view of ascertaining if there were any similarity of dose between what would be required in this disease and in that of scarlet fever, the dose being regulated to cause (1) a hindering of growth of the bacterium; (2) to cause a cessation of growth: and (3) to kill outright; for I concluded that if there were anything like unity in amount my success in my prophylactic treatment would be accounted for. I therefore had a table prepared, based, first, upon the weight of the body. I then allowed ⅛ for the average amount of blood contained therein, and calculated therefrom the approximate amount of carbolic acid that would have to be administered to produce the three separate effects described; and afterwards compared the doses with the one that I was in the habit of giving to my patients suffering from scarlet fever at varying ages.

TABLE I.—*Table showing the Effect of Carbolic Acid on Anthrax Bacillus, and Compared with the Amount of Carbolic Acid given in Scarlet Fever.*

Average weight of body in children and adults.	Amount of blood, ⅛ of weight of body.	Amount of carbolic acid given in scarlet fever in 24 hours.	Number of grains to hinder growth in anthrax bacillus 1/60.	Number of grains to destroy growth of anthrax bacillus 1/60.	Excess or deficiency. To hinder growth.	Excess or deficiency. To destroy growth.
st. lb.	lb.	Grains.				
3 3	3½	30	19½	28½	+ 10½	+ 1½
4 1	4½	36	25	36	+ 11	0
7 4	7½	60	43½	64	+ 16½	- 4
8 0	8½	60	48	70	+ 12	- 10
9 13	10½	60	60½	88½	- ½	- 28½
10 8	11½	60	69½	94½	- 4½	- 34½

In the above table the amount required to kill the anthrax bacillus is omitted, being too large to administer to a patient; but it should be borne in mind that the bacillus was placed under the most favoured conditions to establish robust growth, that it had not the vital antagonistic condition of the blood to contend with, and hence a much larger quantity of carbolic acid was necessary to produce the above results. It will be perceived that to a child from three to five years of age I gave thirty grains of carbolic acid in twenty-four hours, which would be ten and a half grains *more* than is requisite to effect the hindering of growth of the anthrax bacillus, and one and a half more than sufficient to stop its growth. In children from eight to ten years, averaging 4 st. 1 lb., thirty-six grains would be the amount given in the twenty-four hours, being eleven and a half more than necessary to effect the first purpose on the anthrax bacillus, and just sufficient for the second. Coming to those weighing 7 st. 4 lb., the average weight of young people, the dose to scarlet fever patients would be increased to five grains, or sixty in the twenty-four hours; and here we have plus sixteen for the first purpose and minus only four and a half for the second. It is not till we come to 9 st. 13 lb. that the amount given is barely sufficient to hinder growth, and twenty-eight and a half grains *less* than necessary to stop it altogether. In a person weighing 10 st. 8 lb.—the highest calculation made—there is only a deficiency of four and a half grains in the first column, but thirty-four and three-quarters in the second.

This table, of course, is but a basis upon which to ground certain broad inferences as to dose and effect; but I venture to think that the nearness of the dose in the first few years of childhood is of great value, demonstrating, as it does, that in the case of the anthrax bacillus its virulence would be seriously impaired by a dose smaller than that given in scarlet fever, and by analogical reasoning (on the ground that the bacillus of anthrax is of a very resisting nature) we might be justified in assuming that a very much smaller dose would be required to produce a far greater effect on the scarlet fever bacterium. There is, however, a very important point to be noted in the above table, and one apparently fatal to any conclusions we might wish to draw therefrom, and that is, that in the case of the anthrax bacillus the requisite quantity of carbolic acid required to produce the various effects described in the experiments is added at once in its entirety with the nutrient material, whereas in scarlet fever it is divided into twelve parts, and these distributed over twenty-four hours. This apparently fatal objection is met from several points of view; first, I think, there are good grounds for believing that the scarlet fever bacterium has much less resisting power than that of anthrax, and I am led to hold this opinion by observing the condition of the urine in a thoroughly carbolised patient. It must surely be conceded that there is some very powerful germicidal influence at work when the putrescent decomposition of urine—passed by a person suffering from this zymotic disease—is in many cases delayed for several days, and, secondly, prevented from assuming that highly offensive odour (so well known to us all), however long it is kept. We can hardly assert that there is a less antiseptic condition of the blood than of the urine, and if the blood is in this condition it must surely prove, in a great measure, inhibitory to bacterial growth and activity, remembering that "their power to produce disease may be influenced by a trivial alteration in the conditions of life." Then, though we know nothing concerning this bacterium, there is the ascertained fact that a person taking scarlet fever from a carbolised patient *invariably* has a milder attack, demonstrating that a feebler micro-organism has come into existence; and as it is reasonable to assume that the anthrax bacillus is of a more virulent type than that of scarlet fever a much smaller amount would be required to attenuate it—i.e., diminish its virulent power. Then we have to remember that the vital condition of the blood (that vital condition which is termed its life and exists only during the life of the animal) has an inherent antagonism to bacterial growth, therefore with the aid of a germicide of even feebler power than that used in experiments outside the body, bacterial activity would be still further hindered; and it has been proved by experiment that it takes one-third less of carbolic acid to destroy bacterial filaments taken direct from the blood than is required for those grown in nutrient broth, and so we at length get within a measurable distance of a much more moderate dose to effect the attenuated and germicidal powers required by my table than is required for the anthrax bacillus.

There is one other remaining point of importance to be noted. Cohn states that bacterial increase by the usual method of fission is so great that if only two were produced from one bacterium every hour their multiplication would amount to the almost incredible number of 4772 billions in three days. Further observation proves that this fission occurs every twenty minutes. Now each of these, whether more or less in number, would be produced in a fluid antagonistic to bacterial growth, and not under circumstances which would probably weaken the germicide ultimately, but in a fluid which would every two hours be subject to a renewal of the germicidal power. Hence this progeny would in time become "attenuated"—i.e., lose more or less the power of exciting disease, and if not completely attenuated would nevertheless have diminished virulent powers, and so approach that attenuated virulence called a "*vaccine*"; for, as Pasteur remarks, "each cultivation of the attenuated bacterium is a 'vaccine' for the more virulent—that is to say, capable of producing a more benign malady." Why, therefore, should we acknowledge the power of carbolic acid to attenuate and bring into the condition of a "vaccine" the progeny of the anthrax

Digitized by Google

bacillus and deny the same power in the case of the bacterium of scarlet fever?

Such a line of argument would appear to me to be somewhat untenable, contrary to scientific truth, and irrational. I think, therefore, I am fully justified in my belief that carbolic acid given in scarlet fever *does* produce a virus capable of exciting a more benign malady, and without having absolutely witnessed with the physical eye the attenuation of the scarlet fever bacterium by carbolic acid, I contend that the results I have obtained do by analogical reasoning justify my assumption that such is produced, and that the bacterium so attenuated is, in fact, a "vaccine" endowed with all the beneficial results that accrue to such attenuated cultivations. In full confidence of these results ensuing I assert that isolation in scarlet fever is both unnecessary and inexpedient, and have in consequence given up isolating my patients, and feel that I am fully justified by the results of this method in the following cases.

CASE 1.—This case was certainly one of the most unfavourable for experiment. The father of the children suffered from curvature of the spine, and therefore a tuberculous tendency in the children would probably be inferred. The mother was of the sanguine type, highly nervous, and constitutionally delicate. All the children were of the blonde type—thin, pale, lymphatic, always requiring cod-liver oil. The two elder ones had taken scarlet fever some two years previously, when all of the others were carbolised and isolated, and escaped infection. Last year in a fresh locality one of them contracted scarlet fever from that hotbed of zymotic contagium, the board schools. I immediately gave the child carbolic acid, also the remaining two, and on the second day instructed the mother to bring the unaffected children into the sick room. The next day I learnt that they were so terrified that they could not be induced to enter. However, on urging the matter strongly they occupied the chamber, with the result that both took scarlet fever. The first day the pulse and temperature ran high, but on the second the attack suddenly collapsed, and the children were well somewhat more rapidly than usual. In this case had not my confidence in the value of carbolic acid been unassailable I should have had doubts about the wisdom of the procedure (when I found the initial stage so violent), but I was able to assure the mother, who was much frightened, that all would end favourably, and she subsequently acknowledged the wisdom of the proceeding.

CASE 2.—This case was equally instructive. On a former occasion two out of a family of four contracted scarlet fever, the remaining two took carbolic acid, were isolated, and escaped. Last year, in a new house and locality, one of these contracted the disease. The child was duly carbolised and then the other, semi-carbolised, was admitted to the room, spending all the day there, and this was continued until a prolonged desquamation was completed and the house disinfected, yet this fourth child was never attacked.

CASE 3.—Scarlet fever broke out in a house where there was a family of five children, only one of whom had previously been attacked some three years before. After carbolising the patient, and giving the uninfected ones carbolic acid, these were admitted to the room, and remained in it the greater part of the day. One child only, one year old, did not take the acid. All have remained free from attack. Singularly the one who had previously been infected did not take any medicine, and she was attacked with a slight diphtheritic sore-throat.

CASE 4.—I saw a patient suffering from scarlet fever in a family of six. After carbolising the patient, and giving the remaining five the acid, they were all allowed in the room on the second day, and I saw three of them on the bed together on one of my visits. Nevertheless, none of them took it. The house was disinfected, and no further outbreak has occurred. This was six months ago.

CASE 5.—A child, aged eight years, took scarlet fever, and in thirty-six hours the urine showed that she was carbolised. The next day a child barely two years old was attacked, and one and a half grains of carbolic acid was given every two hours. Her urine was soon discoloured. The remaining child, aged four years, took carbolic acid twice a day, played and slept in the room, and so far remains well. The mother had never had scarlet fever, and she also took the acid. There is no evidence of further infection.

So far, then, I have exposed fourteen persons to the direct contagium of scarlet fever and only two have been infected, which is at the rate of about 14? per cent.; and if facts are worth anything for the purpose of demonstrating truths I think I have fully proved that if a patient is duly carbolised from the initial stage (and I make this a great point), and all non-infected persons take small doses of the acid, the risk of infection is very small indeed, and if the contagion does find entrance into the system the attack is invariably mild. Why, then, should we isolate the patient? I contend that it is rather our duty to do all that we can to spread the contraction of this attenuated virus to all the other children in the house, knowing that they will have a mild attack, be immune for the future, and the chance of a prolonged illness is *nil*, whilst that of the appearance of a sequela is about 1 to 1000. But this is by no means all. If they escape infection they may at a later period contract, perchance, a virulent attack with all the subsequent disastrous consequences. One such case is painfully present to my mind.

CASE 6.—There was a family of two only—a boy and a girl. The boy took scarlet fever, was carbolised, and when desquamation was completed the house was disinfected. The girl was semi-carbolised and did not come into contact with her brother until then. Some time afterwards she contracted scarlet fever at school, had the usual vomiting and purging, which the parents attributed to a cold, and she was allowed to go out on a bleak day. The scarlet fever was suppressed and she died a few hours after I was called in.

This case has made me consider the question whether it is quite wise to semi-carbolise the unaffected children at all in a house where scarlet fever has made its appearance, but rather to allow them to enter freely the sick chamber, in the hope that the attenuated virus from the carbolised patient (without being further attenuated in the semi-carbolised) will be sufficient to induce a mild attack, for it is certain that when semi-carbolised the risk of receiving the contagion is very small indeed. On the other hand, we can never be quite certain what response a child's system will make to a zymotic poison. We have all seen mild cases give rise to virulent ones in almost every zymotic. We see it also in vaccination. Two babies apparently alike in physical constitution may be vaccinated from the same vaccine pock, yet on the eighth day one will present a small, well-defined inflammatory area around the vaccine, whilst the other will exhibit a hard indurated inflammation from shoulder to elbow. The introduced zymotic vaccine has been benign in one case, but has produced a virulent type in the other. I have therefore concluded for the future to *diminish* the dose to the unaffected to about one grain, in the hope that this will allow of infection, and, if so, on the earliest appearance to at once give the full dose for scarlet fever. The only exception to this that I think of possibly adopting, after more experience; is that if the first outbreak shows a decidedly mild type to give no carbolic acid to the unaffected, for it shows that we have but a feeble micro-organism to deal with; whereas if the first case shows anything like the virulent type then full semi-carbolism should be at once adopted.

The more, then, we isolate the uninfected the less chance is there of this attenuated bacterium taking up its abode in them and producing a more benign malady, and so protecting them for life. Hence isolation is quite unnecessary. And it is inexpedient. True, I have laid it down as a law not to be broken that the semi-carbolised children when mixing with the enfeebled patient shall not hold any communication with others foreign to the household, and that the open-air exercise necessary for them shall be taken in the garden. Where this is impossible, few gardens existing in overcrowded cities, I have directed those in charge of them to allow no inter-communication with others in the street, and I do this—though it is quite contrary to my theory and belief—because I do not think it right to force my opinions, however beneficial they may be, upon others. Nevertheless, I hold that the more freely the contagion from a carbolised scarlet fever patient is diffused the better it will be for the welfare of the community at large, and if this course is universally adopted scarlet fever will in time be no longer the dreaded zymotic it is at present. I am quite aware that I am making very startling statements, that deeply-rooted prejudice will both hinder and thwart the inauguration of this plan of treatment, that many will look upon it as absolutely Quixotic, and that it will take a long time to overcome both professional and public sentiment, so dreaded is the very name of scarlet fever. Nevertheless, scientific therapeutic medicine must prevail in the end.

A CASE OF SPONTANEOUS ANEURYSM OF THE RADIAL ARTERY IN THE TABATIÈRE: TREATMENT BY EXCISION OF THE SAC; RECOVERY.

BY ROBERT BRAMWELL SMITH, M.R.C.S. ENG.

ON Jan. 25:h, 1896, I was called to see a woman who was suffering from hemiplegia of the right side. Speech and deglutition were affected. I was told that two weeks previously she had had a stroke whilst engaged in household duties. On examining the right arm I noticed a fluctuating swelling about the size of a large marble in the space known as the "tabatière anatomique." Near the back and outer side of the wrist joint this swelling had all the classical signs of an aneurysm. After about three months treatment by rest and the administration of iodide of potassium the patient improved so much that she was able to use her limbs fairly well and her speech gradually returned. I then elicited the following history:—She was fifty-seven years of age, married, of mixed Spanish and English blood, and a dressmaker by occupation. At the age of fourteen years she had had her right leg amputated at the knee for incurable disease of the foot. She had had fourteen confinements at full term, the forceps being used in every case. Twice craniotomy had been performed and twelve children were born alive. Nine of the children were then alive and all were apparently healthy and of adult age. Two had died in youth from scarlet fever and one from bronchitis. She had had no miscarriages and there was no history of syphilis. At the age of twenty-seven years (thirty years previously) she had had a "stroke." Paralysis of one side followed and she lost her sight for ten days. This occurred a fortnight after one of her confinements. On examination a well-marked systolic bruit was to be heard at the junction of the sternum and the manubrium, which was conveyed along the carotids with great distinctness. On passing the finger-tips over the vessels of the neck the peculiar rosary-like feel of atheroma was experienced. Not the slightest sign of degeneration could be detected by the fingers in either the brachial, radial or ulnar arteries of either side. Arcus senilis was well developed. The patient first noticed the swelling at the wrist about five years previously, her attention being drawn to it by the uneasy sensation produced when she used her scissors. There was no history of injury whatever. I had the patient under observation for the rest of the year 1896. On March 18th I began to treat the aneurysm as the patient felt a great deal of pain proceeding up the arm from the swelling. Pressure over the radial artery above the sac together with pressure below and upon the sac by means of an elastic bandage was applied on three different occasions for some hours each time and discontinued when pain was too severe for the patient to bear. Pressure was kept up on the radial artery in the intervals. At the end of three weeks the pulsations had ceased altogether in the sac. Unfortunately, the cure was not permanent; probably from voluntary movement of the thumb the clot was disturbed and pulsation began to show itself. Rather strangely, at the time that the pulsation was noticed the patient had a third, though slighter, attack of hemiplegia. In addition to the paralysis there were several shorter attacks of spasm of the muscles of the arm on the affected side. The arm was brought round and the muscles were held in a condition of tonic contraction. There was well-marked anæsthesia all down the right side. The symptoms of paralysis left her by November, when she was persuaded to see Mr. Thomas Jones at the Manchester Royal Infirmary and he advised excision. As the patient now had great pain and as her hand was useless I determined to operate after showing the case at a meeting of the Manchester Medical Society. On Dec. 26th the patient was put under chloroform and the brachial artery being controlled by digital pressure I made an incision of three inches in length directly over the swelling. The superficial structures and fascia were cut through and several large veins were cut and clamped. The sac was exposed, occupying the space between the tendons of the extensor ossis metacarpi pollicis, extensor primi internodii pollicis, and extensor secundi internodii pollicis, passing under the latter tendon. After some dissection, owing to the tumour extending into the substance of the abductor indicis two branches were seen proceeding from the distal end of the sac, one being probably the continuation of the radial artery to the deep palmar arch. These, and the radial artery itself, which was much enlarged, were tied with recently boiled silk, and the wound was sutured with silkworm gut. No drainage tube was used, and the wound was dressed with Lister's double cyanide gauze.

Two weeks after the operation the wound had healed by first intention, except where one suture had been disturbed. In three weeks the wound was healed and the patient, contrary to my advice, was at work with her machine. Within a month she had done a day's washing. The aneurysm was of about the size of a large marble or a chestnut and of the sacculated variety. It was partly filled with a firmish white clot. The points of interest are: 1. The rarity of non-traumatic aneurysm in the radial artery. 2. The absence of any satisfactory reason for the formation of an aneurysm in such situation. My own opinion is that the aneurysm was due to embolism and probably dated much further back than the period of five years during which the patient had noticed it. I believe the increased prominence of the symptoms were due to degenerative changes peculiar to the patient's age and that nature was attempting a cure in an imperfect way. I cannot help thinking that the clot in the sac being disturbed had something to do with the second and third attacks of hemiplegia. 3. The advantages of excision in accessible cases over other methods. The patient was a most unpromising subject for operative measures or chloroform narcosis, yet she made a perfect recovery without a single bad symptom.

Manchester.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON A CASE OF CHOLESTEATOMA OF THE ATTIC OF TWENTY YEARS' DURATION SIMULATING DISEASE OF THE MASTOID PROCESS.

BY ADOLPH BRONNER, M.D.,

SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL; LARYNGOLOGIST TO THE BRADFORD ROYAL INFIRMARY.

A STRONG, healthy man, aged thirty-one years, saw me in January, 1896. There had been a discharge from the right ear for more than twenty years. Three times (ten, six, and two years ago) there had been a large, painful swelling behind the ear, which was incised. Frequently during the last few months there had been severe attacks of pain in the ear, accompanied by swelling and tenderness over the mastoid region. When I saw the patient there was an extensive fluctuating swelling behind the right ear, extending downwards to below the mastoid process, and upwards and forwards into the temporal region. The temperature was 101° F. and the pulse was 89. There was a copious, offensive discharge from the ear, and a fairly large perforation of the membrana tympani. On Feb. 5th a large incision was made into the abscess down on to the bone. Some pus escaped. A large quantity of unhealthy granulation tissue was removed by scissors and a sharp spoon. There was no fistula of the mastoid process, but the bone was rough in some places. I opened up the mastoid antrum and surrounding cells, which, to my great surprise, were apparently normal. The incision was then prolonged upwards round the upper part of the auricle, the cutaneous auditory meatus was cut through, and the ear was pulled downwards. The middle ear was thus exposed. A grey soft mass seemed to protrude into the upper part of the middle ear and a probe could be passed upwards for over half an inch. This was evidently the greatly distended attic. The upper wall of the osseous auditory

Digitized by Google

meatus and the outer wall of the attic were then chiselled away and a cavity the size of a large cherry was exposed, which was filled with soft caseous matter. The walls of the cavity were smooth. The projecting edges were removed and the wound and cavity were plugged with iodoform gauze. The discharge for the first few days was extremely offensive, in spite of the local application of glycerine of carbolic acid and a perchloride of mercury lotion (1 in 100). The wound was plugged from above daily for three weeks and allowed to heal up from below by granulation. In two months the wound had completely healed with the exception of a small fistula above the auricle which was kept open by silver wire. In five months the discharge from the ear ceased. There has been no recurrence of the discharge or swelling. The hearing was so improved that a watch which was heard at a distance of one inch from the ear before the operation could afterwards be heard two inches away.

The interesting features of this case seem to be (1) that the attic had been affected for twenty years and the disease had not spread into the mastoid antrum or cerebral cavity; (2) that disease of the attic should have caused such extensive and repeated attacks of periostitis of the mastoid process; (3) that the cholesteatoma should have formed in the attic and not in the mastoid cells, as is generally the case; and (4) that the wound was kept open and allowed to heal up from below by granulation, as suggested by McEwen and Victor Horsley. The method generally adopted is to try to keep a large permanent opening above or behind the ear.

Bradford.

DEATH OF FŒTUS IN UTERO FROM GUNSHOT WOUND; RECOVERY OF THE MOTHER.

BY SAMUEL WILLIAM ROBINSON, M.D., B.CH. DUBL.,
MEDICAL OFFICER, NORTH-EAST ARGENTINE RAILWAY.

ON the morning of Aug. 25th, 1894, while on a pleasure trip in the country, about fifteen miles from the town of Empedrado, in this province, I was called to see a young woman, aged eighteen years, married eight months, who had been shot in the abdomen. On arrival I found her lying on a bed with two or three women about her, but with very little expression of shock or suffering. On examination I found a bullet wound, made by a fair-sized ball, a little to the right of the umbilicus and slightly below. There was no bleeding more than an odd drop of venous blood for a radius of two inches round the wound; there was extravasation of liquid in the tissues, at the time thought to be blood, but now believed to have been amniotic fluid. The abdomen was very pendulous, as is generally the case with the peasantry of these parts. I gave her opium and sent for instruments in case of necessity. About one hour afterwards labour set in, and went on slowly until 2 o'clock next morning, when, the woman being fairly exhausted and the pains weak, the os being sufficiently dilated, she was delivered by long forceps. The post-partum hæmorrhage being very sharp there was no time to examine the child, which had already begun to decompose. The hand was next passed into the uterus, and an opening in the anterior wall could be distinctly felt, with a part of the membranes prolapsed and held tight in the same. This no attempt was made to loosen, but the membranes were torn off close to the uterine walls, and the hand withdrawn with placenta which was loose in the cavity. The uterus was washed out with hot antiseptic solution (creoline), and ergot was given. On examining the child, which was at almost full time, it was found that the ball had entered the right shoulder by the junction of the acromion process with the scapula, and had come out in the left iliac region, drawing with it a coil of small intestine which was not wounded. As there was but one wound perceptible in the uterus the question arose: Where had the ball gone to? However, this was easily settled, as, on examining the clots, &c., it was found in the débris. The mother made an uninterrupted recovery, her treatment consisting in the application of iodoform to the external wound, which healed without suppuration, as all wounds do which have been made by a bullet having a great velocity (this one had been fired at a distance of three metres), ordinary antiseptic treatment being used. The uterus was washed out twice a day with a solution of creoline. The mother gave birth to a live child in 1895, and must have had little trouble, as she was attended by a native midwife.

Monte Caseros, Province of Corrientes, Argentine Republic, South America.

NOTES ON A CASE OF ASPHYXIA NEONATORUM IN WHICH THE HEART CONTINUED TO BEAT FOR MORE THAN FOUR HOURS WITHOUT THE RESPIRATORY FUNCTION HAVING ACTED.

BY JOHN MACKENZIE, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.

ON Aug. 11th, 1894, I was called to attend in confinement a woman aged forty years. On examination the presentation was found to be occipito-posterior. The os was rigid and the uterine contractions were slow and feeble. The patient, a soft, flabby woman, had been in labour since the early morning (it was then 5 P.M.) and was much exhausted. The os having been dilated, delivery was effected by the forceps. The passage of the fœtus through the parturient canal took about half an hour. The delay was chiefly due to traction being used only during the pains. In the interval the blades were loosely held to obviate the effect of prolonged pressure on the fœtal head. When the child (a male) was born the funis was round his neck, the face was livid, the lips were blue (livida pallida), the heart was beating feebly, respiration was absent, and there was no pulsation in the cord. In the hope of relieving stasis in the fœtal channels the cord was cut and left unligatured, but no blood escaped. Considering this a very grave sign, and to guard against the possibility of mistaking any adventitious sounds for the heart sounds, I carefully auscultated and found the latter to be quite clear. I immediately began artificial respiration, practising alternately Marshall Hall's and Silvester's methods, and douched the infant with hot and cold water, &c. Remembering also Mr. Victor Horsley's advice in cases of arrested respiration from cerebral pressure, I applied hot fomentation to the head, at the same time continuing artificial respiration. For fully two hours I persevered with the ordinary treatment for asphyxia neonatorum, means I had never once seen before to fail with such a regular and even cardiac action; still there was not the faintest sign of respiration. Loth to give up the struggle I resolved on another manœuvre. The child was placed in the recumbent position with the head and neck extended, the tongue was pulled out, the jaws were kept apart, and I gently blew air through his mouth and nostrils. With every effort the chest and abdomen expanded as in natural breathing. Counter-pressure with the left hand on the lower part of the thorax expelled the air with a whistling noise through the glottis. It was noted that counter-pressure on the abdomen alone failed to produce this noise. Soon the heart's action considerably improved, becoming louder and quicker to such an extent that I could easily see its impulse against the chest-wall, yet there was no effort at voluntary breathing, the face and lips remaining the same. Exceedingly puzzled at the phenomenon of a heart beating for hours without the faintest appearance of respiration, the idea struck me that in all likelihood the heart was stimulated mechanically through the terminal filaments of the vagus by air passing along the œsophagus into the stomach, and not as I had imagined by the presence of oxygen in the fœtal blood. To clear up this doubt I managed to pass air into the stomach by means of a small gum-elastic catheter. Whilst doing so the heart beats fell back to the original condition, slow and feeble, just ticking in the distance, but on resuming blowing air through the mouth and nostrils the heart responded and improved as already described. This I did over and over again, and at last in despair (for it was now 10 P.M.), and to my regret, I left the infant who then had a strong, bounding pulse. How long the heart continued beating I am unable to say. I found the child dead next morning.

Remarks.—The above notes were written at the time, three years ago. After reading Sir Dyce Duckworth's paper, read at the Moscow Congress and published in THE LANCET of Sept. 4th, on Cases of Cerebral Disease in which the Function of Respiration entirely ceases for some Hours before that of the Circulation I thought this case of sufficient interest for publication.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

WESTMINSTER HOSPITAL.

A CASE OF RUPTURED HYDRO-ENCEPHALOCELE WITH EXTREME CONGENITAL HYDROCEPHALUS; EXCISION.

(Under the care of Mr. WALTER SPENCER.)

IN the following very interesting case the protruded membranes formed so large a swelling that rupture took place as the child was born; to this rupture is undoubtedly to be attributed the septic infection which occurred. The operation effectually prevented any further loss of cerebro-spinal fluid or any further absorption of septic organism. Removal of these large protrusions is always indicated, but it not rarely happens, as in this case, that the condition of brain which is present is incompatible with the child's continued existence. In many cases the interference with the intracranial pressure which results from the removal of the swelling is the cause of convulsions and death. For the notes of this case we are indebted to Dr. F. Kenneth Wilson, house surgeon.

A female child, aged thirty-six hours, was admitted into Westminster Hospital on Aug. 3rd, 1897. The mother, a primipara, was reported to have been in the second stage of labour, after eight months of pregnancy, when the swelling of the child's head was first perceived. Dr. Sydney Wright, under whose care the mother was, used forceps to deliver the arrested head. When born the tumour was about the size of the child's head. Dr. Wright sent the case to the hospital. On admission the child's head appeared to be of normal dimensions, but the sagittal and coronal sutures, including the posterior fontanelle, were still unclosed to the extent of a finger's breadth, and the occipital bone was in the same plane as the nape of the neck, no occipital prominence being present. Attached to the occipital bone was a soft, fluctuating swelling, somewhat less than one half the size of the head; it was covered with skin of the same thickness as the rest of the scalp. The skin was somewhat bruised and lacerated, and a little fluid was seen to be oozing from one point on the tumour. The child's temperature was 101° F. It was not considered advisable to administer any anæsthetic. Mr. Spencer made an incision round the base of the tumour and turned the skin back; the pedicle was cleared as far as possible, and then it was pinched between the finger and thumb. This pressure caused no disturbance, and no solid matter could be felt in its interior. The pedicle was then transfixed by a round needle carrying a strong silk ligature; the halves of the ligature were interlocked and the pedicle was tied, and another ligature was placed round the pedicle as a whole. The tumour was removed and the flaps which had been raised were drawn together. No more cerebro-spinal fluid escaped. On examination the tumour removed was found to consist of a thin-walled sac with a smooth inner surface; it contained blood-stained serous fluid. The child appeared to be none the worse for the operation and subsequently took milk well and a little brandy. The next day (Aug. 4th), as the temperature had risen to 104°, the sutures were removed from the middle of the wound, but only normal coagulated exudation was found and no pus. During the whole of that day and the next (the 5th) the temperature remained between 102·5° and 104·5°. On several occasions on these two days the child had slight attacks of general convulsions. The temperature remained high in spite of sponging, reaching 104° on the fourth day (the 6th), and on the morning of the fifth day after admission the child died. The intracranial pressure was normal throughout; certainly it was never excessive.

Necropsy.—At the post-mortem examination the parietal bones and the frontal bone were found to be unduly separate but partly ossified. The occipital bone was complete except for an opening admitting the thumb at the junction of the inter-parietal and supra-occipital elements of the bone. On opening the skull the two hemispheres formed distended sacs with very imperfectly marked convolutions. Between the hemispheres was the roof of the third ventricle of the usual reddish colour. This roof of the third ventricle extended backwards over the corpora quadrigemina, and was constricted at the tentorium, the opening in which was of the usual size. On opening the posterior fossa all that was at first seen was a distended sac formed by the roof of the fourth ventricle. As the middle lobe of the cerebellum was absent, the roof of the fourth ventricle was attached to the opening in the occipital bone corresponding with the ligature of the pedicle on the exterior. The large sac, which consisted therefore of the dilated third ventricle, the aqueduct of Sylvius, and the fourth ventricle, contained a greenish serous fluid without any sign of exudation, pus, or fibrin. In this brain were absent the corpus callosum, the fornix, the roof of the aqueduct, and the vermis of the cerebellum. The stage of development in which the arrest had taken place corresponded to one of His's drawings of a fœtus of two and a half months, reproduced in Quain's "Anatomy."[1] The hydro-encephalocele was therefore a protrusion from the roof of the fourth ventricle in the position usually occupied by the middle lobe of the cerebellum. It is remarkable that the skull should have been so well formed, being, except for the aperture in the occipital bone, the skull of an infant in the eighth month of pregnancy. The high temperature had commenced before admission, and was apparently due to general septic infection, as there was no evidence of inflammation about the wound or within the skull. The operation did not appear to affect the child at all. The care that was taken to ligature the pedicle of the tumour prevented any further loss of cerebro-spinal fluid.

JAMSETJEE JEJEEBHOY HOSPITAL, BOMBAY.

A CASE OF OBSTRUCTION OF THE PYLORUS FROM SPASM OF THE SPHINCTER; LORETA'S OPERATION; RECOVERY.

(Under the care of Surgeon-Lieutenant-Colonel W. K. HATCH.)

DIGITAL dilatation of the pylorus, or Loreta's operation as it is usually called, has been used in a fair number of cases, but it is less frequently employed at the present time than it was a few years ago. When the stricture of the pylorus is very rigid the dilatation by the finger is rather apt to cause rupture of the wall with a fatal result, and even when the dilatation has been effected with safety re-contraction of the pyloric orifice may occur and lead to obstruction at that point as early as the fifth day.[2] For these reasons Loreta's operation has been in great part replaced by pyloroplasty, or the Heineke-Mikulicz operation. In the following noteworthy case spasm of the sphincter may have been, as Surgeon-Lieutenant-Colonel Hatch suggests, the cause of the obstruction, but the stenosis may have been due to cicatrisation of a small shallow ulcer, possibly traumatic in origin.

The patient, a Hindoo, twenty-eight years of age, was admitted into the medical wards of the hospital under the care of Surgeon-Captain Childe on July 6th, 1897, and was transferred to the surgical wards on Aug. 6th. He had been treated during that time medically, but with no improvement, and an operation was advised. He stated that he had suffered from burning pain in the epigastrium and vomiting at night for the last two years, and had consulted several qualified and unqualified practitioners, but had received no benefit; previously to this his health had been good. He attributed his illness to the fact that he was unable to get sufficient food during the day, but drank large quantities of water; in the evening he had his food about 8 P.M., and at midnight he usually commenced to vomit a considerable quantity of water and particles of food; this was followed by a burning pain in the epigastrium. When admitted into the surgical wards he was thin and weighed 89½ lb., but was not anæmic. The pulse was small and regular, the tongue was coated and fissured, and the gums were spongy. He

[1] Tenth edition, vol. i., part i., p. 60.
[2] THE LANCET, Jan. 9th, 1892, p. 87.

Digitized by Google

said that he felt extremely miserable on account of his prolonged illness and would be glad to die. Vomiting and burning pain at the epigastrium were the two symptoms of which he complained. The lungs and the heart were healthy and the liver was not enlarged. The abdomen was concave and the muscles were thin and flaccid; after food it became somewhat distended below the left costal border. No tumour could be felt, though the weakness of the abdominal muscles allowed every part to be easily examined. The stomach was found by percussion to be somewhat enlarged, but succussion sounds were not elicited. The appetite was rather increased, but there was no vomiting during the day. He was fed at 9 A.M., 2 P.M., and 6 P.M. About two hours after this last meal he usually complained of giddiness and eructations; this was followed by vomiting, about two cupfuls of fluid altogether, and was succeeded by pain of a burning character in the epigastrium. The bowels were constipated, the stools being hard and scanty. No blood had ever been vomited or passed by the bowel. On Aug. 11th the patient was chloroformed and a longitudinal incision three inches long was made in the linea alba, beginning an inch below the ensiform cartilage; the stomach at once presented. Examination of the pyloric end and of the duodenum did not clear up matters, the parts appearing to be perfectly healthy. Surgeon-Lieutenant-Colonel Hatch therefore opened the stomach near the pylorus and, introducing the finger, examined carefully the mucous membrane in all directions. Search was then made for the pyloric opening, but it was so tightly closed that for some time no opening could be discovered. At last a slight slit-like depression could be felt, and the finger being gradually pushed against this forced open the sphincter, which was then forcibly dilated; a ring-like constriction which gradually gave way was felt, but no real hypertrophy could be distinctly made out. A second finger could not be introduced, but the single finger moved freely from side to side. The stomach and abdominal incisions were then closed. From that time the vomiting and other symptoms ceased and the patient made a satisfactory recovery, the wound healing soundly. He now takes the same food as ordinary patients and has regained his strength to a considerable extent. He was not allowed to sit up for a month, and solid food was given for the first time fourteen days after the operation. The temperature rose to 100° F. on the evening of the operation, but fell next day to normal, and continued so until the present time, the patient being now perfectly well.

Remarks by Surgeon-Lieutenant-Colonel HATCH.—Native patients, particularly Hindoos, are very reluctant as a rule to undergo any abdominal operation, and the fear of this generally prevents them from coming to hospital even in cases of intestinal obstruction until their friends have tried all ordinary medicines. Consequently our statistics in abdominal surgery do not show very satisfactory results as compared with those of English hospitals. It was only when this man was tired of his life that he applied for relief, and I believe this case to be the first in which Loreta's operation has been performed in Bombay. As no ulcer or growth was met with I conclude that this was a case of pure spasm of the pylorus, and I may remark that ulcer of the stomach is extremely rare in Bombay either in males or females; only once have I met with a case of perforating ulcer, and in that instance I operated unsuccessfully. Although anæmia and disorder of digestion are very common among native females, the rarity of ulcer in India as compared with its frequency in England is extremely interesting.

LEEDS GENERAL INFIRMARY.

A CASE OF LIGATURE OF THE EXTERNAL ILIAC ARTERY FOR ANEURYSM BY THE TRANSPERITONEAL METHOD.

(Under the care of Mr. W. H. BROWN.)

THE introduction of the transperitoneal method of ligature of the iliac arteries was due to Dr. Dennis, of New York.[1] Among its advantages are the less danger to the peritoneum and other structures that it entails, the greater ease with which the operation can be performed and the choice which it gives to the surgeon of the best position for the ligature. In many cases also the older incision is rendered exceedingly difficult by the presence of the aneurysm for which the ligature of the artery is required. There is in the transperitoneal incision certainly the added risk of sepsis in the peritoneal cavity, but with even ordinary care this risk is slight.

A man, aged forty-five years, was admitted into the infirmary suffering from an aneurysm situated at the junction of the external iliac and the femoral arteries. The aneurysm was about the size of a hen's egg. Under ether Mr. Brown opened the abdomen in the line of the external iliac artery, cutting through the peritoneum. He tied the vessel midway between the bifurcation of the common iliac and Poupart's ligament, a silk ligature being used. Pulsation was immediately stopped. The peritoneum was then stitched together and the abdominal wound closed in the ordinary way. The patient made an uninterrupted recovery and is now walking about.

Remarks by Mr. BROWN.—This is the second time that I have had occasion to tie the external iliac artery for aneurysm, and in each case I have operated by the transperitoneal operation and with a good result. I think the method has many advantages over the older operation, and provided strict cleanliness is maintained is not more likely to be attended with disaster. In both cases the ordinary operation would have been difficult, if not impossible, owing to the position of the swelling.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Presidential Address.—Posterior Basic Meningitis of Infants.—Multiple Spontaneous Fractures.—Exhibition of Specimens.

THE first meeting of this society for this session was held on Oct. 19th, the President, Dr. J. F. PAYNE, being in the chair.

The PRESIDENT, after thanking the members of the society for electing him to the chair, referred to the objects of the society. He said that some had criticised the name of the society, holding that the term pathology is much too wide for the subjects which come under its notice. But the association of the idea of morbid anatomy with the term pathology, although regrettable as giving an incomplete view, is so bound up with medical literature of the past that it is difficult to see what other name could have been given to it by its founders and no one could reasonably propose that the name of the society should now be changed even if a more appropriate one could be selected. The limitation of topics is largely due to the fundamental rule of the society that except in rare instances no communication should be received which is not accompanied by a material specimen of some kind, a rule assuring greater authority and trustworthiness in the communications which are admitted. The advantages of this rule have been recognised by other societies, and the demonstration of experiments and the exhibition of living cases have become established institutions. The study of disease or pathology in its widest sense has always rested on two foundations—(1) the study of the material changes which are found associated with disease either as cause or effect; and (2) the study of the dynamical or functional changes. These two lines of thought may be more or less clearly distinguished through the whole history of medicine, sometimes one and sometimes the other being predominant. One may be called the anatomical school and the other the functional or dynamical. The Pathological Society belongs to the anatomical school. The utility of the study of material changes in the body has been questioned by some eminent men both in ancient and modern times. Even Sydenham was in opposition to, or at least out of sympathy with, the anatomical school. He avowed that he had never devoted himself to minute investigations in anatomy, which he considered to have no application to the art of healing; and of pathological anatomy he speaks with something like contempt. He says: "Others have more pompously and speciously prosecuted the promoting of this art by searching into the bowels of dead and living creatures to find out the seeds of disease destroying them, but with how little success such endeavours have been and are likely to be attended I shall in some measure make appear"; and his friend Locke (who was an

Digitized by Google

accomplished physician as well as a great philosopher) follows in the same strain: "All that anatomy can do is to show us the gross and sensible parts of the body or the vapid and dead juices, all which after the most diligent search will be no more able to direct a physician how to cure a disease than how to make a man." Had he lived in the present century Sydenham would probably have taken a different view of morbid anatomy. Probably his example had something to do with the neglect of anatomy by English physicians in the eighteenth century when his influence was supreme. And even in spite of the triumphs of morbid anatomy in the present century there has been a certain undercurrent of disparagement or neglect which has not ceased even in our own time. The term "morbid anatomy" should not be used as restricted to post-mortem examinations, but as including the investigation of the material changes of tissues and organs by whatever means this investigation can best be carried out. The morbid anatomy of the ovaries has been chiefly elucidated by specimens removed during life, and the same is true of the pathology of the vermiform process and of tumours. It is a mistake to call all that is observed during life clinical and only that which is observed after death pathological. Physical diagnosis, including not only auscultation, but also the simpler investigation of abdominal organs, is really a study of morbid anatomy. Auscultation was introduced by Laennec, a profound pathological anatomist, who first showed how the facts of morbid anatomy, known by post-mortem examination, could be detected and studied in the chest of a living patient. It was only when physical signs were found systematically connected with known changes in the internal organs that they became significant. It is not too much to say that in diseases of the internal organs, other things being equal, the most precise diagnosis will be that of the physician who can form to himself the most precise mental picture of the state of a diseased organ and who knows also how to infer the existence of that state by observations during life of men like Sir William Jenner, Sir Samuel Wilks, Dr. Bristowe, and Dr. Murchison. It is claimed that while there are other methods of investigation, morbid anatomy supplies the most solid and fundamental facts, and that without it modern clinical medicine could not exist. In addition to its value in medical practice, morbid anatomy has played a great part in the advance of the scientific side of medicine, as shown conspicuously in recent years by the triumphs of bacteriology. The bacteriologist when making cultures is a botanist, when he detects bacilli in the tissues of man or animals is a morbid anatomist, and when studying the production of immunity in living animals is a clinical investigator, but he can seldom dispense with pathological anatomy and histology. Dr. Payne expressed the hope that the society would continue in its present course of bringing the results of pathological research into relation with practical medicine, and stating them in such a manner as to be intelligible to all who take an interest in pathology, even if they are unable to take part in original research.

Dr. G. F. STILL exhibited slides and cultures illustrating the bacteriology of the Posterior Basic Meningitis of Infants. He said that the disease occurred chiefly in the first year of life, and had been recognised recently as a definite disease both clinically and as regards its morbid anatomy, which is quite distinct from ordinary suppurative cerebro-spinal meningitis of pneumococcal infection or the septic meningitis from nose or ear disease. The cases are sporadic and occur most frequently in the spring. Seven consecutive cases were examined bacteriologically after death, and in all except one, which died three and a half months after the onset, the same organism was found. Subsequently a pure growth of the organism was obtained from each lateral ventricle in a child who had been ill over three months. In five out of the six cases it was obtained as a pure growth. The organism is a diplococcus, smaller than the pneumococcus, occasionally found in the cells, but more frequently floating in masses in the fluid. No definite capsule has been demonstrated. It stains easily by ordinary methods, but is decolourised by Gram's process. It is aerobic, and grows well at 37° C., but not at the ordinary temperature of the room. Rapid growth occurs on glycerine agar and agar-agar, which are the most convenient media, giving rise to slightly raised, greyish-white colonies, which are viscid and tend to run together to form rose-shaped patches. The growth is much thicker and more opaque, and the colonies are larger than those of the pneumococcus grown under similar conditions, and it also differs in not causing coagulation of milk. The organism grows well in broth, but very slightly on blood serum. It exhibits unusual vitality, living from thirty to forty days. It is seldom present in large numbers, and is easily overlooked unless a large piece of lymph is spread on the medium. Even when no cultures could be obtained from the adhesions at the base Dr. Still had found the diplococcus present in the fluid in the lateral ventricles. He had never succeeded in demonstrating it in the blood during life. Eleven inoculations had been made on mice, rabbits, and guinea-pigs. Subcutaneous injections produced no effect, and after intra-peritoneal injection the guinea-pigs merely refused their food, but none of them died. Dr. Still thought that the organism was certainly not the pneumococcus, but that it closely resembled the diplococcus intracellularis which had been described by Weichselbaum in connexion with epidemic cerebro-spinal meningitis. It differs in its strong vitality, in its growth in broth, and in its being non-toxic to mice and guinea-pigs. But Dr. Still held that these differences might easily be explained by a natural variation such as has been artificially produced in other micro-organisms, and that if this view is correct these cases must be regarded as sporadic cases of the same disease as epidemic cerebro-spinal meningitis.

Mr. C. SPURRELL showed specimens of Multiple Spontaneous Fractures taken from a married woman, thirty-seven years of age. She was of a neurotic temperament and, giving a long history of an indefinite illness, was admitted to the Poplar and Stepney Sick Asylum for spontaneous fracture of the right femur on March 6th, 1896. There was softening and deformity of the skeleton and the pelvis was especially distorted. She died from cystitis and septic nephritis on July 14th, 1897, and then had three fractures of the left femur, one of the right femur, fifth metatarsal, right and left tibia and fibula, right radius and ulna and six ribs on the left side. At the necropsy the femur was almost wanting in places, and all the bones could be easily cut with a knife. The medullary cavity of the bones of the upper extremities was diminished in size. Microscopically the bone appeared to be absorbed by giant cells and its place taken by hyaline cartilage and fibrous tissue.

Mr. EDGAR WILLETT showed specimens from a case of Multiple Spontaneous Fractures, the history of which has already been recorded by Mr. Langton,[1] from a man who was thirty years of age at the time of his death. He had had a succession of fractures from the time he was eleven years of age, in some of which bony union and in others fibrous union only occurred. When he was twenty-eight years of age a spindle-celled sarcoma developed at the seats of the fractures in his right humerus and the limb was amputated, but he died some months later from secondary deposits. The specimens showed fractures united by fibrous tissue and much displacement. There was no evidence of growth in any of the fractures except those in the right humerus.—Mr. J. R. LUNN remarked on the absence of nervous symptoms in the case related by Mr. Spurrell. The case bore some resemblance to one which he had described in the St. Thomas's Hospital Reports as acute osteitis deformans. The condition was very difficult to distinguish from osteomalacia.—Mr. D'ARCY POWER asked if the sarcoma was considered to be an accidental complication in Mr. Willett's case. He quoted the case of a boy who had a spontaneous fracture at the age of eight years, and afterwards had a succession of such fractures. He was still alive, and no light had been thrown on the pathology of the condition.

The following card specimens were exhibited:—

Dr. CALVERT and Mr. T. STRANGEWAYS PIGG: Melanotic Sarcomata in Various Organs.

Mr. D'ARCY POWER: Empyema of the Antrum in a Child aged eight weeks.

Dr. VOELCKER: (1) Carcinomata of the Heart and of the Pylorus; (2) Ulcerative Colitis; and (3) Uterus Bicornis.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Dysmenorrhœa.

A MEETING of this society was held on Oct. 14th, the President, Mr. MAYO ROBSON, being in the chair.

Dr. MACNAUGHTON-JONES showed a Uterus, the seat of both Carcinoma and Fibroid, removed by vaginal hysterectomy. The patient, a multipara aged fifty-three, had had no

[1] Transactions of the Clinical Society, vol. xxix.

Digitized by Google

symptom except hæmorrhage. Microscopic examination demonstrated the malignant character of the growth. While the operation was in progress the fibroid of the fundus offered considerable difficulties, being left behind owing to the tearing away of the friable lower portion of the uterus. He delivered the fibroid after compressing it with Doyen's forceps.—Mr. TENISON COLLINS (Cardiff) showed (1) a Foreign Body removed from the Bladder, consisting of a Pencil-holder round which a Stone had formed, and which had been *in situ* for two and a half years without causing symptoms and was discovered accidentally while dilating the cervix for stenosis; and (2) two Uteri removed by vaginal hysterectomy for Carcinoma.—Dr. CLEMENT GODSON showed a Glass Button-hole Flower-holder which he had recently removed from a Bladder. It had caused retention of urine. The patient came of a neurotic family.—The PRESIDENT, Dr. PURCELL, and Mr. BOWREMAN JESSETT, Mr. SKENE KEITH, and Mr. O'CALLAGHAN, joined in the discussion on the specimens.

Mr. SKENE KEITH read a paper on Dysmenorrhœa, which was limited to the treatment of uterine dysmenorrhœa. It was pointed out that the pain was caused, not by a stricture, but by the bending of the uterus *plus* the thickening of the mucous membrane and the congestion naturally present at the commencement of menstruation. The necessity of thoroughly trying general treatment before even thinking of anything local was insisted on, and the general treatment recommended was chiefly with the view of keeping the patient warm and thus preventing internal congestion. For the severe cases where all remedial measures had failed local treatment by stem pessaries, dilating in its various forms, division of the cervix, division with stitching, Dudley's operation, and Apostoli's treatment were considered; special attention being directed to the two last as being newer and less known than the others.—The PRESIDENT had had a very satisfactory experience of Dudley's operation, with which he had become acquainted through Dr. George Keith's paper before the society. It was simple and effective. He related a case illustrating its advantage over other procedures, and stated that he had not yet had a failure. He employed chromicized catgut sutures which did not require removal.—Dr. W. TRAVERS had had experience of the operation in four cases; he also had learned it from Dr. George Keith and indeed generally thought of it as "Keith's operation." One case, a neurotic woman and hitherto sterile, had been almost bedridden for seven years. After operation the first two periods were painless; at the third there was some return of pain; after this she got quite well and became pregnant.—Dr. HEYWOOD SMITH thought that a combination of incision, dilatation, and the use of the stem-pessary often answered very well. Dilatation alone did not usually lead to permanent improvement. The mistake was often made of incising too freely; the mucous membrane should be incised, just nicking the subjacent parts, and the dilators should then be introduced, after which a sterilised glass stem-pessary might be left in for a few days.—Mr. TENISON COLLINS said that when Dr. George Keith read his paper he was much worried over a case in which he had already dilated twice without avail. Dudley's operation led to complete cure. In two other cases the result had been equally satisfactory, and one of the two patients had since become pregnant and was delivered of a living child at term.—Dr. ARTHUR GILES acknowledged his indebtedness also to Dr. George Keith for his knowledge of Dudley's operation, which he had performed in about a dozen cases. In nearly all the result had been most satisfactory. In one or two there had not been much improvement, probably either because constitutional disorders had become established which took some time to subside or because the dysmenorrhœa was partly of central nervous origin. In one case all kinds of treatment for dysmenorrhœa had been tried for many years; the patient had been married twelve years and was thought to be sterile. After the operation the first two periods were absolutely free from pain, and she then became pregnant. He agreed with Mr. Skene Keith as to the importance of preventive hygiene in the early years of puberty. He thought that they needed here the coöperation of mothers, who should be impressed with the idea that dysmenorrhœa was no necessary portion of a girl's early menstrual years.—Dr. SCHACHT thought it would be very useful if at some future time all who had had experience of this operation would tabulate their results and send them in. He would willingly analyse and summarise such records for publication in the journal.—Mr. BOWREMAN JESSETT called attention to the fact that many young girls of from fifteen to seventeen years of age suffered from dysmenorrhœa, from which they were relieved by medical means, and great care should be used in selecting cases. It would be a great pity if the impression was created that the society advocated this or any other operation for all such cases. In cases of pure stenosis it was not indicated, but the plan suggested by Dr. Heywood Smith would probably answer quite well.—The discussion was then adjourned to the following meeting.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

Election of Officers.—The Purvis Oration.

THE first meeting of the forty-second session of this society was held on Oct. 8th at the Royal Kent Dispensary.

The annual report having been adopted, the following were elected officers for the ensuing year:—President: Mr. W. Arbuthnot Lane. Vice-Presidents: Dr. Morgan Dockrell and Dr. Edward H. Ezard. Council: Dr. R. Scholefield, Dr. George Herschell, Dr. John Mackern, Dr. Thomas C. Meggison, Mr. C. J. Parke, Dr. P. C. Scott, and Dr. Septimus Sunderland. Treasurer: Mr. J. P. Purvis. Secretary: Dr. J. P. Henry. Librarian: Dr. H. Bowen Williams.

Dr. G. H. SAVAGE then delivered the Purvis Oration. Having pointed out the immense progress which had resulted from the recognition of the facts of evolution he proceeded to consider the mental disorders associated with evolution and dissolution. The so-called ethnic division of idiots was suggested by the late Dr. Langdon Down. Some European idiots resemble Malays, Tartars, Mongols or Negroes. These cases happen to be human sports and not in any way to indicate that Europeans are the pinnacles of all civilisation. The Chinese may be able to return the compliment and say that certain Chinese idiots resemble Europeans. In idiot asylums one can meet with defects ranging from the slighter moral, intellectual or sensory defects to complete absence of all but the organic nerve reflexes. A few children come into the world simply reflex machines and not always good at reflex acts. Some seem without hunger or the desire for food and are quite unable to feed themselves or seek for food. Other children seem never to develop beyond the eating stage. Such seem to be morally defective from the first and may become adroit thieves. The young animal whose centre is his stomach is essentially egotistical. The deficient development of any altruistic feeling arises from defective development of the reproductive function. In another set of cases there is not complete arrest of development, but there is retardation of evolution. Some of these seem to be developed on one side at the cost of the others; they may be mechanical inventors or distinguished athletes, while reading, writing, and spelling may be almost impossibilities. There are moral idiots and moral imbeciles—children to whom truth, honesty, and any regard for others cannot be taught. Some such are brilliant musicians or infant prodigies of one kind or another. It is at the adolescent period that the neuroses, truly so-called, are most evident, such as hysteria and hypochondriasis, which almost always has a sexual basis. The patient thinks he has ruined his health by self-indulgence, or exaggerates some personal peculiarity. If so much fuss were not made about masturbation we should see fewer disastrous effects. The most delicate, most sensitive, and most conscientious are those most likely to indulge to their own injury. More harm follows the moral than the physical trouble. In some cases the worry rather than the physical effect leads to melancholia which is often suicidal. In general paralysis of the insane the reduction of mental power proceeds from the last and most specialised acquirement to the less developed, and in the end may leave little beyond a reflex machine. The inability to judge of one's own condition is very striking. As few old men recognise their failing powers till they are gone so the general paralytic is quite unable to recognise his state. Dissolution is the complement of evolution and is equally instructive. The mind gives way in different ways according to its physical environment, more rapidly in the city than in the country. Some nervous systems are calculated to work for a certain time and then break down. Neurotic heredity in many cases

Digitized by Google

shows itself in this tendency to break down prematurely. Dissolution is the reverse process to evolution and it follows the same lines in the reverse order, the most highly specialised functions failing first. In many cases the memory of recent events is lost while that of long past events is made clearer. With early signs of dissolution hysteria and sexual desire long absent seem to flicker up and often lead to trouble. In some cases there are marked sensory disorder and hallucinations of sight or hearing, and a tendency to dwell on supposed defects of the sexual organs. Co-related to this is the strange reversion which is often met with, so that the tastes, habits, and ways of youth reappear with age. In both evolution and dissolution we meet with disorders due to want of power and others depending on loss of control. King Lear and Don Quixote represent the very poles of senile dissolution. The oration was illustrated by a number of cases representing the different types of disease described.—Dr. EZARD, Dr. TAYLOR, Dr. BOWEN WILLIAMS Dr. MEGGISON, and Mr. ROBERTS having spoken, votes of thanks to the orator and out going officers were passed.—Dr. SAVAGE and Mr. PURVIS replied.

Reviews and Notices of Books.

Die Geschwülste des Nervensystems: Eine Klinische Studie. Von Dr. LUDWIG BRUNS. Berlin: S. Krager. 1897. (*Tumours of the Nervous System: A Clinical Study.* By Dr. LUDWIG BRUNS Berlin: S. Krager. Glasgow: F. Bauermeister. 1897.) Price 12*s.*

THERE is abundant scope for clinical and pathological investigation in the domain of new growths implicating the several parts of the nervous system. Indeed, it is not too much to say that our knowledge of cerebro-spinal functions has been considerably amplified by such studies, whilst conversely the more exact determination of the localisation of these functions has aided materially in the diagnosis of the position of tumours and their amenability to radical removal. Varying much in their nature and rate of growth, tumours which involve brain or spinal cord present also great differences in situation, and therefore produce manifestations in associated signs and symptoms that demand close study for their differentiation. The records of cases illustrating every variety of new growths are sufficiently extensive to afford material for a most interesting and instructive monograph, which by collating and systematising the facts they describe cannot fail to be of service to neurological science and practice. This task has been well fulfilled by Dr. Ludwig Bruns, of Hanover, who has succeeded in presenting a survey of the subject that is sure to be appreciated. His subject matter falls naturally under the three heads of (1) Tumours of the Brain; (2) Tumours of the Spinal Cord; and (3) Tumours of the Nerves, each department being dealt with first from the anatomical and then from the clinical standpoint.

The thoroughness with which Dr. Bruns discusses the subject may be shown by a brief survey of the chapters devoted to cerebral tumours. In the first place he devotes many pages to the description of the various forms of tumour, pointing out the characteristics of gliomata and sarcomata, which he shows to be by far the most frequent forms, and also describing in detail gummata and tuberculous growths, as well as the less frequent examples, such as psammoma and cholesteatoma. Nor does he omit mention of cysticerci and echinococci, simple cysts, and aneurysms. The interesting question of the relationship of traumatism to cerebral tumours is debated with impartiality, inclining rather to the conclusion, even in cases where no symptoms arose until after the infliction of the injury, that this latter acted rather to reveal the presence of a growth (mostly gliomatous) which had been latent prior to that occurrence. At the same time he cannot doubt the occasional direct relationship and perhaps the more frequent excitation to increased activity of the new growth by the agency of traumatism. He does not think, as some do, that a hæmatoma can be converted into sarcomatous or other organised formation. The effects of a tumour upon the brain substance, whether by compression or infiltration, or the supervention of inflammatory changes, of softening and of hæmorrhage, are next described, and the all-important subject of symptomatology is entered upon. This is discussed in a thoroughly scientific as well as exhaustive manner. The general symptoms of cerebral tumour are held to be definite and characteristic. They comprise, in the first place, headache, the most frequent and the most important of all, the character and site of which are by no means indicative of the seat of disease (unless an occipital headache be accompanied by retraction of the head), and attributable to irritation of the nerves supplying the dura mater owing to the increased tension of the membrane; vertigo, a symptom of less frequency than headache, but of value when it occurs; vomiting, fairly constant, and generally sequential to headache; slowness of pulse, slow and irregular respiration, mental disturbance, chiefly dulness and hebetude. Convulsions, especially those of Jacksonian type, and optic papillitis are also fully described. Dr. Bruns is decidedly of opinion that the last-named characteristic is not of inflammatory origin, and that the old term of "choked disc" (Stauungs-papilla) is really a more accurate description of its nature. He gives various reasons for thus reverting to a doctrine that has been discarded by many high authorities, and some of them have certainly the merit of cogency. One of these is the fact, established by the recent successful ablation of brain-tumours, that the removal of the growth, or even the operation of trephining, which reduces the intracranial pressure, has been followed by a subsidence of the so-called "optic neuritis." The next portion of this chapter deals with local symptoms, and the effects of tumours in each part of the brain in turn are described. It is obviously impossible here to follow him through all these descriptions, the study of which proves how precise has become the means for localising lesions in this organ. It is pointed out that tumours in the frontal region produce ataxic symptoms similar to those due to cerebellar growths, and a valuable tabular comparison is given of the associated symptoms which enable the differential diagnosis to be clearly established. This question of diagnosis is also very fully treated subsequently, both from the point of view of the general signs of tumour as distinguished from those of abscess, meningitis, sclerosis, hysteria, &c., and from that of the locality and nature of the growth. Lastly, the subject of treatment is amply discussed, a full review being given of the experiences of surgical intervention.

The tumours which may involve the spinal cord are as various in their nature as those liable to affect the brain, but the effects they produce are less numerous, and their differentiation in consequence more simple. Yet the importance of their study is also great, since an exact determination of their situation and a satisfactory proof of their extra-medullary nature may enable them to be removed by operation. Intra-medullary growths, associated as these often are with syringomyelia, have a symptomatology of their own, of which the most prominent features are the bilateral distribution of muscular atrophy and paralysis, the dissociation of tactile, thermal, and algesic sensory defects, and the occurrence of cutaneous and other trophic disorders or of vaso-motor derangements. Such growths are of course beyond the sphere of ablation, but those which grow from membranes and are limited in extent may be readily removed. The tumours of peripheral nerves are more summarily treated; but the

Digitized by Google

section dealing with them gives many interesting facts upon neuromata of special nerve-trunks, besides those remarkable cases of multiple neuromata of which molluscum fibrosum forms the most striking example. The monograph is undoubtedly one which fills a place in medical literature hardly perhaps so fully occupied before. It abounds in facts of high interest and importance and has been prepared with manifest care as well as good judgment.

Saint Bartholomew's Hospital Reports. Edited by SAMUEL WEST, M.D. Oxon., and W. J. WALSHAM, F.R.C.S. Eng. Vol. XXXII. London: Smith, Elder, and Co. 1897. Pp. xlix. and 548. Price to subscribers, 6*s.*; to non-subscribers, 8*s.* 6*d.*

THE first place in this volume is given to a sympathetic "In Memoriam" notice of Sir George Murray Humphry by Mr. C. B. Lockwood, and this is followed by a similar appreciation of Mr. Morrant Baker by Mr. Alfred Willett. Mr. Thomas J. Horder contributes a collection of 258 Aphorisms enunciated by Dr. Gee during the years 1895 and 1896; they vary of course greatly in interest, but many of them are of distinct value and well deserve to be rescued from oblivion. It would be of interest if similar collections were made from the utterances of other physicians.

Every surgeon must have experienced the difficulty of diagnosing between true intestinal obstruction and some forms of colic, and Dr. A. M. Mitchell gives notes of four cases of enteritis and colic in which the resemblance of the symptoms present to those of intestinal obstruction was so great that in three out of the four cases a laparotomy was performed, but no obstruction of the bowel was found; a useful table of the chief points in the four cases is added for comparison. Mr. Edgar Willett has a short paper on the Roseolous Rash which appears in some cases during the administration of ether; it shows itself about four minutes after the commencement of the administration and lasts for about ten minutes. It is more common in women than in men, and occurs in about 5 per cent. of all cases. Mr. McAdam Eccles contributes a paper on Hernia of the Vermiform Appendix; he has collected twenty-nine cases of this condition; in sixteen of these the appendix was alone in the hernial sac and was acutely strangulated, in seven cases it was alone in the sac but was inflamed, in four cases it was alone in the sac and unaffected, and in two cases it was in the sac with other viscera, and acute inflammation of the appendix existed. It is probable that the presence of the vermiform appendix in the sac of a hernia is by no means rare. Dr. F. W. Andrewes has written a valuable paper on the occurrence of the Diphtheria Bacillus in a series of cases of sore-throat amongst the female staff of the hospital. He examined systematically every case of sore-throat of whatever type which presented itself to him in his capacity of medical attendant to the nursing staff. The conclusions at which he arrives are as follows: the clinical characters are sufficient for the purpose of diagnosis of diphtheria in a large proportion of the cases, but in some cases, perhaps a ninth of the whole number, bacteriological examination proves the presence of the diphtheria bacillus although the clinical aspect of the case is not that of diphtheria. Dr. Andrewes considers that absence of virulence in a bacillus is no indication that it is not a true diphtheria bacillus, and that the spread of diphtheria is chiefly due to those slight unrecognised cases which clinically would not be considered to be cases of the disease. In one case the cultures of the bacillus when first isolated from the throat were non-virulent, but after some months of cultivation they became highly virulent. This case is in itself sufficient to show that virulence is quite untrustworthy as a criterion. Space will not permit of detailed references to all the papers contained in the volume, but we may mention a useful paper on Thiersch Grafting, by Dr. H. J. Paterson; an elaborate article on the Leucocytosis of Scarlet Fever, by Dr. R. Sevestre; and a valuable paper, by Mr. H. Holmes and Dr. A. A. Kanthack, on the Relationship of Cardiac Hypertrophy and Œdema to Chronic Renal Disease.

Dr. Morley Fletcher's paper on the Etiology of Chorea is also interesting. He concludes from the consideration of the records of 307 in-patients and 273 out-patients suffering from the disease that chorea is a manifestation of rheumatic fever, but that many other causes may coöperate in the production of the disease. Dr. Arthur Heath records four cases of Congenital Absence of the Radius in one family. Dr. H. H. Tooth has contributed the results of his investigations into the Pathology of Alcoholic Neuritis, and arrives at the conclusions that in some cases, though symptoms of alcoholic paraplegia have been present for a considerable period, yet post mortem no alteration of the nerve fibres can be found, that the change in the nerves when it does occur is always degenerative in character and never inflammatory, and that marked pigmentation of the cells of the anterior cornua is a common feature. The article is accompanied by a very copious bibliography of the subject. Descriptions of the specimens added to the museum during the year ending September, 1896, and statistical tables of the patients under treatment during 1895 by the medical registrar (Dr. W. P. Herringham) and the surgical registrar (Mr. James Berry) conclude the volume. These tables are very elaborate and must represent a vast amount of labour expended in their compilation. Details of a large proportion of the surgical cases are also given and add much to the value of the surgical registrar's report. An interesting table is that of the amputations with the percentage of deaths during the ten years 1886 to 1895 inclusive.

It is often said that hospital reports are of little value, but a volume like the one before us completely disproves any such statement.

Health in Africa: A Medical Handbook for European Travellers and Residents, embracing a Study of Malarial Fever as it is Found in British Central Africa. By D. KERR CROSS, M.B., C.M., F.R.G.S., Medical Officer for British Central Africa Protectorate. With an Introduction by Sir HARRY JOHNSTON, K.C.B., H.B.M.'s Commissioner for British Central Africa Protectorate. With numerous Illustrations. London: James Nisbet and Co., Ltd. 1897. Price 3*s.* 6*d.*

THE author of this laudable attempt to be of service to those who live in Africa on the outskirts of civilisation tells us in his preface that ten years' residence in British Central Africa as a medical man has impressed him with the need of a small handbook on health. He points out several reasons why this should be so, both in reference to the personal health and well-being of the new-comer to malarial regions and in reference to others, as, for example, the natives of Africa, by whom any European is regarded as a medical man to whom they frequently appeal for advice and medical aid when sick. In a volume like the present, embracing so many and such variety of subjects, which are treated in a necessarily condensed but plain and useful fashion, it is difficult to select passages illustrative of the way in which its author has fulfilled his task. A work of this kind is, and must be, in great part a compilation, but no pains seem to have been spared to render the information useful and trustworthy and up to date. It is very far from being, however, a simple compilation or sample of bookmaking, for the information is conveyed in an intelligent, scientific spirit. That part of the chapter on Specific Fevers which treats of malarial fever strikes us as good. Malarial diseases, although very unequally distributed over the globe, are the most ubiquitous of all diseases; they recede as

Digitized by Google

civilisation advances; and drainage, cultivation of the soil, and the rendering of the surface of it more or less hard and impervious, have nearly abolished them in Europe. In climates like those of Africa it is far otherwise, and this will, it is to be feared, long remain so. The account of these fevers—their different forms and varieties, symptomatology, clinical features, treatment, and causation—is well done, and a lucid and interesting, if condensed, explanation of the life-history of the micro-organism with which they are associated—the plasmodium malariæ—is given. Black-water fever, or bilious hæmoglobinuria, is also shortly but well described. We notice, by the way, a typographical error at page 50, in which "retention" is used for "retraction" of the testes. The book contains a large amount of very useful and practical information on a variety of topics; it is very well illustrated and has a good index, and it may be honestly recommended as an excellent guide to those for whom it is designed.

LIBRARY TABLE.

A First Series of Fifty-four Consecutive Ovariotomies, with Fifty-three Recoveries. By A. C. BUTLER-SMYTHE, F.R.C.S. Edin., F.R.C.P. Edin., Senior Surgeon to the Grosvenor Hospital for Women and Children, Senior Surgeon to Out-patients, Samaritan Free Hospital for Women and Children. London: J. & A. Churchill. 1897. Price 6*s.* 6*d.*—The author says in the preface: "When I had completed my first fifty cases I decided to wait and see if I could obtain a clear run of fifty successful operations, inasmuch as I had been unfortunate enough to lose my fourth patient. Having now succeeded in attaining my object I venture to publish the results." There is always a little difficulty in classifying cases that have to be published under the title of "Ovariotomy." The term is here defined as meaning "removal of solid tumours of the ovary, cystomata, broad ligament tumours, parovarian, tubo-ovarian cysts, and cystic ovaries." There are a few general remarks on the operation, and on the significance of certain symptoms, at the beginning of the book. The author believes in flushing out the peritoneum in certain cases—for instance, where pus has been met with during the operation. Many operators, however, believe that such flushing tends rather to diffuse offensive matters to distant parts of the peritoneum previously unsoiled, and rely entirely on sponging to remove the pus. As regards drainage, another point as to which there is a good deal of difference of opinion, the author evidently believes it to be frequently required, as it was employed in twenty-five out of his fifty-four cases. We do not agree with the author in his views about the pulse in patients after ovariotomy. He considers that "too much importance is attached to rapidity of the pulse." ..... "In the absence of further indications, a rapid pulse should not be looked upon as denoting danger." Certainly a rapid pulse is generally of less importance during the first two days after ovariotomy than it is a day or two later. No doubt also the size of the pulse must be considered when estimating the importance of its rapidity. But, with these qualifications, we think most operators agree that the state of the pulse is by far the most important guide as to the condition of the patient after ovariotomy and similar operations. Mr. Butler-Smythe adopts a somewhat picturesque style in describing his cases, which reminds us of Mr. Charles Wyndham recounting the numerous objects of his admiration in *The Case of Rebellious Susan*. Thus "Mrs. M., a short woman; ..... M. W., a tall woman; ..... E. C., a thin woman; ..... E. W., a medium-sized woman; ..... J. R., a dark-haired woman; ..... A. B., a brown-haired woman; ..... M. P., a stout woman with iron-grey hair; ..... A. E., a putty-faced woman; ..... E. R., a pasty-faced woman; ..... (these last three were not included if we remember rightly in Mr. Wyndham's series); M. T., a fair-haired woman; ..... L. C., a full-faced woman; ..... M. G., a merry-faced woman," &c. The last case given is E. H., a widow, whose appearance the author, no doubt for good reasons of his own, does not venture to describe. A faithful record of a series of operations is always interesting, especially to those engaged in similar work, and to this rule Mr. Butler-Smythe's little book is no exception.

Sight-testing for the G. P. By F. DAVIDSON. Pp. 36. London: A. La Riviere. Price 2*s.* 6*d.*—In this little book, the title of which is inelegant, the subject of glasses and of sight testing is given from an optician's point of view, and the statements made are sufficiently correct for all ordinary cases. They would probably enable the country practitioner, who has not had an opportunity of attending an ophthalmic hospital or the eye wards of a general hospital (if there be such), to determine a simple case of myopia, or hypermetropia, or of astigmatism. We doubt, however, whether it is quite within the province of an optician to pose as the instructor of medical men in these respects. The physiological factor is, of course, overlooked, and the patient who is suffering from spasm of the muscle of accommodation consequent on hypermetropia, might easily have concave glasses ordered for him to his detriment, as there is no caution given in regard to that condition. Again, the maxim here laid down, "Advise the invariable use of glasses for reading and all near work in myopia," must depend for its correct application on the degree of myopia. Many persons who are moderately myopic have got into the habit of holding the book at a certain distance, and are indisposed to wear glasses which make a change in their position requisite. Once more, it is stated that astigmatism is *always* corrected by means of cylindrical lenses; but, alas, there are cases of irregular astigmatism in which no form of cylindrical lens that can be ground will afford much help. Fortunately, however, these are rare.

Analytical Records
FROM
THE LANCET LABORATORY.

PICNIC CONDENSED MILK.

(THE CONDENSED MILK COMPANY OF HOLLAND, LIMITED, ROTTERDAM, AND 21, MINCING-LANE, E.C.)

PERHAPS the most satisfactory feature in the composition of this condensed milk is, as our analysis shows, the excellent proportion of fat or cream-equivalent which it contains. The fat amounted to 12·00 per cent. and the mineral matters to 1·80 per cent. On diluting the milk with 3½ parts of water the resulting milk presented the composition of genuine rich milk, containing nearly 4 per cent. of fat. For infant feeding it is directed to dilute the milk seven times, in which case a milk of the following composition is obtained: Total solids (including cane sugar), 15 83 per cent.; fat, 1·90 per cent.; mineral matters, 0 30 per cent. The sample was in a sound and excellent condition and free from preservatives other than cane sugar. It is not in any degree deficient in the nourishing constituents of rich cow's milk.

ANTI-DIABETIC BREAD (FOUGERON).

(MESSRS. FOUGERON AND CO., 30, RUE ST. AUGUSTIN, PARIS. LONDON AGENCY: R. HOWDEN, 23, GRACECHURCH-STREET, E.C.)

On examination this bread proved to be somewhat heavily loaded with fatty matter, while on boiling a portion in hot water the resulting liquid when cooled gave a strong starch

Digitized by Google

reaction with iodine. The basis of the bread is evidently almond flour. We are not sure whether the bread is offered as a remedy for the disease or as simply a suitable food for the diabetic. In a pamphlet accompanying the sample submitted to us it is said that the use of this bread decreases the glycosuria "in large proportions," and "in the case of diabetics where the urine has a small trace of sugar it causes it to disappear." We ask, Why? The bread contains a distinct quantity of starch and has a not very agreeable oily taste.

ST. RAPHAEL QUINQUINA WINES.

(E. DELACOSTE, 16, NEWMAN-STREET, OXFORD-STREET, W.)

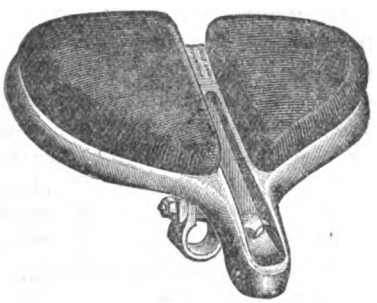
A red wine and a white wine were submitted to us for examination. The results of analysis were as follows. Red wine: Alcohol, by weight 15·33 per cent., by volume 18·88 per cent., equal to proof spirit 33·08 per cent.; extractives, 7·36 per cent.; mineral matter, 0·30 per cent. White wine: Alcohol, by weight 15·67 per cent., by volume 19·28 per cent., equal to proof spirit 33·79 per cent.; extractives, 13·82 per cent.; mineral matter, 0·30 per cent. Neither of the wines yielded quinine on extraction with a suitable solvent, but a residue was obtained, which was bitter to the taste and somewhat pungent. This residue with potassium tri-iodide gave a reddish-brown precipitate, a reaction which is characteristic of the cinchona alkaloids. The solution of the residue, however, in sulphuric acid did not exhibit fluorescence. Both samples had "crusted" to a small extent at the time they were received. The wine selected as a basis in each case was of excellent quality and of generous character, possessing good, fruity, and slightly aromatic flavour.

MARVINE GELOIDS.

(THE MARVINE SYNDICATE, LIMITED, 28, ELDON-STREET, AND BROAD-STREET HOUSE, E.C.)

Complete confirmatory evidence was obtained of the statements made in regard to the composition of these "geloids," or lozenges, as they really are. They possess a pleasant acid flavour and dissolve readily in the mouth, a distinct but pleasant taste of beef extractives and cocoa at the same time being noticeable. The mineral matter obtained on incinerating a "geloid" contained a large proportion of potassium phosphate. Apart from the presence of the other ingredients this soluble salt, as is well known, affords a very refreshing beverage when dissolved in water. Marvine geloids act well as "thirst quenchers," due chiefly to the presence of the acid of lime juice. In addition, they contain well-known nourishing and stimulating ingredients. They keep well, but contain no objectionable preservatives.

LE VIN DÈSILES.



(AGENCY: FASSETT AND JOHNSON, 32, 33, SNOW-HILL, E.C.)

We cannot recognise that this wine is, as stated, a remedy for anything like the great number of complaints enumerated in a pamphlet which accompanied the sample submitted for examination. It doubtless serves as an agreeable restorative and tonic, since it contains the extracts of coca, kola, and cocoa, together with iodo-tannin and phosphate of lime. The excipient is "Special Dèsiles." We had little difficulty in confirming experimentally the presence of the many and various constituents indicated. The composition of the wine was as follows: Absolute alcohol 16·23 per cent., by volume 19·96 per cent., equal to proof spirit 34·98 per cent.; extractives 23·45 per cent.; mineral matters 0·26 per cent. The wine is sweet to the taste and has a strong flavour of coca leaf. It is described as a "Cordial Régénérateur." Its composition is certainly complex, and this is why, we suppose, it is recommended for so many ailments—a recommendation to which we refuse to lend the slightest support.

New Inventions.

THE "CHRISTY" ANATOMICAL BICYCLE SADDLE.

IT is generally conceded that the most important item in a bicycle is the saddle, for upon this depends the comfort of the rider, and it determines in large measure the question whether or not cycling is a healthful or a harmful exercise. The saddle under consideration is built so as to avoid any perineal pressure. As will be seen by the illustration it consists of two pads separated by a groove and the surface lies in a horizontal plane and is not wedge-shaped. The only difference between the saddle intended for a man and that for a woman consists in the peak being slightly shorter in the case of the latter. We have submitted each form of saddle to a competent rider of either sex and have received a favourable report thereon. At first there is a feeling of insecurity, but this very soon wears off after a little practice. The makers are Messrs. Spalding and Bros., 54, Holborn Viaduct, E.C.

THE INDIAN RISING AND THE TIRAH EXPEDITION.

THERE has been some sharp but desultory fighting on the border, on the Samana range, and two squadrons of the 9th Bengal Lancers reconnoitring from Fort Bana in the Khyber fell into an ambuscade and sustained a rather severe loss. The way has now been cleared, after the desperate fighting at Dargai on the 20th, for the advance of the main column of the force for Tirah, and the arrangements for the expedition under Sir William Lockhart have been completed. If we may judge from the samples we have already had of the fighting the advance of the expedition will be stoutly opposed, and the next point to be carried where the tribes are likely to make a stand will be the Sanpagha Pass. Ambuscades and surprises and the extreme difficulty of getting at the enemy in mountain warfare of this kind are the main obstacles to be overcome. One great anxiety connected with the expedition has, as usual, been the transport. While every effort has been made to reduce the amount of baggage and material to the utmost, the number of transport animals accompanying the force is necessarily very large. There will be as little tentage as possible with the troops—that allowed for hospital purposes will be on a very reduced scale, and considering the physical features of the country and the nature of the expedition it cannot be otherwise. We have not yet seen any official list published of the medical *personnel* of the forces and we can only trust that the number of medical officers accompanying the troops will be fully adequate to their requirements. The expedition is on a large and bold scale and must prove a very costly one, but it had become inevitable. The tribes had no excuse whatever for their rising at the present time; they had been subjected to no unjust or aggressive treatment, and they were being paid for keeping the roads and passes open. The movements of the expeditionary force sent for their punishment will be followed with great interest. Nothing can exceed the pluck, loyalty, and devotion of the native army, and the troops—British and Indian—of the expedition are in excellent health and fettle. As the expedition had to be undertaken we trust it will not be regarded simply as a punitive one. The opportunity must be seized for reducing the Afridi and Orakzai tribes to order and for securing some settlement that shall secure the frontier from a repetition of treacherous revolts of this nature. The recalcitrant tribes must be taught that the Indian Government is master, and intends to remain so. Having learnt that lesson it will remain for a wise, judicious, and conciliatory policy to effect the rest.

THE LANCET.

LONDON: SATURDAY, OCTOBER 23, 1897.

THE theme of the notable address delivered by the Harveian Orator at the Royal College of Physicians of London on Monday last was happily chosen, whilst its spirit was consonant with the life-work of the master—our "venerated saint and apostle"—whom it commemorated. With admirable skill Sir WILLIAM ROBERTS showed how intimately bound up with modern civilisation are the methods of scientific inquiry which were practically initiated by HARVEY and his great contemporaries, GALILEO, BACON, and DESCARTES, and he felt justified in doubting whether it were possible for a civilisation so supported to share the fate of those ancient civilisations which have either become wholly extinguished or have remained stagnant and effete. For he pointed out that those ancient civilisations rested upon the cultivation of pursuits that are finite and personal, upon art and letters which seem to be incapable of advance beyond a certain pitch of excellence, and then to suffer decline. To be sure, they may be revived, and the world may yet witness another Renaissance, but they cannot in the nature of things undergo that expansion which in the sphere of science seems well-nigh illimitable. It was far from the orator's intention to institute any comparison between these mainsprings of human thought and endeavour; his admiration for the treasures that have been handed down by the masters of arts and literature proves that he did not disparage the part they had played in the cultivation of mankind; but he truthfully pointed out how some of the most precious masterpieces are those that were produced in dim antiquity, and how far below the heights then attained have fallen the endeavours of all but a few who have since laboured in the same fields.

Exact science—that based on the observation of facts, on experiment, on generalisation and deduction—dates from the time of HARVEY, and during the three centuries that have elapsed it has been undergoing an evolution which within our own time has proceeded with amazing rapidity to the great advantage and welfare of mankind. It may be that its progress will be less rapid in the future, but that it will continue to progress there can be little doubt. Sir WILLIAM ROBERTS, in the skilful exposition of some of the gains which have already accrued from the development of the sciences, expressed no doubts on this score. The spirit and methods of true science are such that when properly pursued they admit of no retrogression. Facts established as facts cannot be shaken; and one discovery of these secrets of Nature which HARVEY exhorted us to seek out leads to another being revealed from her inexhaustible store. Therefore, the Harveian orator has no fears for our modern civilisation, nor does he share the view expressed by the late Professor PEARSON as to its ultimate destiny. The nations that have pursued science can never be overwhelmed by the unscientific. Equally hopeful was his outlook of the effects of a civilisation based on science in promoting peace and improving culture, whilst the very storm and stress which are introduced into modern life by means of this activity are evidence of vigour and vitality as well as of progress.

Thus, then, did the Harveian orator convey a lesson which may well be taken to heart. It is not one indeed which is needed by members of the medical profession. They know too well the immense gains to health and prosperity which have arisen directly from the pursuit of natural science. But there are some persons in these days who seek to disparage science, and write or talk as if the world would have been the better without it. It is to be hoped that such people will embrace the opportunity afforded them by Sir WILLIAM ROBERTS of learning to how great an extent they are dependent on that which they affect to despise. He is no true lover of science who claims for it that which does not rightly belong to it, nor does it befit the follower of science to be arrogant and bigoted. Those who have best contributed to its advance have been men who have pursued it in the spirit of HARVEY, whose life and work have seldom been more happily and tersely sketched than they were in this oration. It is well to commemorate such a man, and it is well for us, too, to be reminded of the great work he did in laying down the first principles of scientific observation which have yielded so much up to the present and promise to yield yet more in the future.

WE dealt last week with the subject of adulteration of food, and drew a few lessons from the mass of interesting material supplied by the twenty-sixth annual report of the Local Government Board which has recently been issued. With the same report under consideration we may now turn our attention to the water-supply of the metropolis. Recent events have contributed largely in bringing the questions of the quality and quantity of the water supplied to London prominently before the public, and in their report Major-General SCOTT deals with quantity and Sir EDWARD FRANKLAND with quality.

In regard to the former section of the subject it is well known that during the last year or so considerable arrangements have been made for increased storage, and this is notably the case with the East London Waterworks Company, while the construction of storage reservoirs near Staines on a very large scale is about to be commenced under Parliamentary powers obtained by three of the metropolitan water companies during the last session of Parliament. The mean daily discharge of the Thames at Kingston is 1,300,000,000 gallons, and the quantity of water daily abstracted for the use of the metropolis is limited to a maximum of 130,000,000 gallons in twenty-four hours. The withdrawal of the quantity taken by the companies "can have no appreciable effect on the *régime* of the river in a general sense." But exceptional droughts in the summer must be taken into account, and it is at this time that the flow of the river is reduced to a minimum while the abstracted quantity approaches a maximum. Proper storage is the

Digitized by Google

only means of coping with this difficulty if the present sources of supply are to be counted upon as adequate for future requirements. This applies with still more force to the Lea, which may be reduced to a stagnating quantity and to a minimum fraught with risks to the public health. Major-General SCOTT rightly emphasises the necessity for enforcing strict conservancy and regulations for sewage farms situated on or near the rivers above the intakes, and for the rejection as far as possible of the water of the Thames and the Lea during periods of rain when the rivers are swollen by surface drainage. These precautions become more and more urgent every year as the population in the river districts increases. Consequently upon the experience of severe frosts during recent years several of the companies have relaid their mains at a greater depth, and considerable advances have been made in extending the system of constant supply. Cisterns, however, cannot be dispensed with; but, at the same time, there should always be a draw tap on the supply pipe so that water can be obtained for drinking and cooking purposes in a pure and cool condition direct from the main. We are surprised to find that in spite of the importance of a good "head" of water being maintained in the mains for the purposes of fire extinction the companies at present are under no statutory obligation.

Sir EDWARD FRANKLAND'S report on the quality of the metropolitan water-supply is full of interesting reading and its purport is decidedly reassuring. No unpalatable or objectionably tinted water was detected during the year. The unfiltered water of the Lea was generally superior in regard to organic matters to that of the Thames. Sir E. FRANKLAND refers to those researches which have shown that zymotic agents are rapidly destroyed in running water, so that the most minute microscopic inspection of the water as it reaches the intake has failed to discover in it a single pathogenic germ. Efficient sand filtration, it is pointed out, would further prevent the passage of such germs into the filtered water even should they arrive in a living condition at the intakes of the companies. Thus, he says, the hygienic objection to the use of filtered water taken from the Thames and Lea is removed. We are quite willing to accept this statement, but only so long as efficient filtration is held to be the highest possible degree of efficiency of which the filters are capable. The organic matter present in river water as delivered in London was according to the construction put upon Sir E. FRANKLAND'S analyses during the past year to a very large extent of vegetable origin. Both the Thames and Lea waters delivered during the year 1896 were somewhat below the average quality of the previous years in regard to organic matters. In regard to suspended matter Sir E. FRANKLAND adds a paragraph which we imagine would not have appeared had not the London County Council's chemists about this time last year published a report in which it was shown by DIBDIN'S micro-filter method that suspended matter identical in character with that occurring in raw Thames water was found in the water drawn from the London public supply. Sir E. FRANKLAND is very precise in demonstrating how all water, even the purest in nature, contains abundance of suspended matter. He adds that the amount of this suspended matter in the *efficiently* filtered river water supplied to the metropolis rarely if ever exceeds 0·0002 gr. in a tumblerful, and therefore in order to imbibe a single grain it would be necessary for the consumer to drink no less than 5000 tumblerfuls of the water. This is a popular way of putting it, which forcibly reminds us of the London County Council's Report in which the amount of suspended matter was calculated in terms of mud containing 90 per cent. moisture.

Sir E FRANKLAND again evidently had Dr. KLEIN'S portion of the London County Council report just referred to in his mind when he pronounced upon the standard of bacteriological purity. He does not consider that the presence of the bacillus coli communis in water is a proof of sewage contamination, because this organism is one of the most ubiquitous and persistent of harmless microbes. We do not think this statement will go without challenge. We are again reminded of the London County Council report in Sir E. FRANKLAND'S expression of opinion that it is of little use to examine the filtered water delivered in London, not only because it is a mixture of the effluents from many filters, but especially because the multiplication of ordinary river and harmless microbes is so rapid that the number is generally increased many fold between the filtration works and the standpipes in London. He supports his argument by the results of experiments which showed that whilst the Lambeth companies' filters were passing water containing only 116 microbes per c.c. a sample drawn from one of their standpipes in the streets contained 1560 in the same volume. Further, as he has previously shown, the results of the bacterioscopic examination of the unfiltered waters again demonstrate the remarkable effect of storage in reducing the number of bacteria. In some instances he found a number of microbes in the water-supply in excess of the standard, and in June, for some unexplained reason, the filtration plants of nearly every metropolitan company were simultaneously unable to perform efficiently their work of bacterial purification. Sir E. FRANKLAND has failed to find an explanation of this singular occurrence. As he reasonably observes, if it had occurred only in one or two cases it might have been attributed to accident or carelessness, but the fact that it occurred in every supply indicates that the cause must be some condition or conditions affecting both the Lea and the Thames.

THE election of Mr. VICTOR HORSLEY, as we said last week, was secured by a substantial majority. He received 6946 votes against 6112 given for Sir WALTER FOSTER—a majority of 834. This result appears to be very satisfactory to the profession as a whole, for Mr. HORSLEY'S opponents recognise in him a man who will support the dignity of direct representation, while his friends have every confidence in his energy and his devotion to the cause of medical reform. If he expresses advanced opinions he will give grounds for them, and it cannot be supposed that one occupying his high position in science will advocate anything that will tend to any deterioration of the educational standards of the profession.

The general lessons of the election are not to be

Digitized by Google

disregarded. It is comparatively gratifying to gather from the report of the Registrar that 59·64 per cent. of the voters did their duty by voting for the candidate they preferred. Of 22,576 voting papers sent out—that is, by the way, just one less than the number issued last year—13,466, or 59·64 per cent., were returned by the voters within the proper time. This is an improvement in the numbers voting equal to 5·42 per cent. of the whole as compared with the election of last year. But it is not wholly satisfactory. It still leaves 8061 voters who have not availed themselves of the privilege conferred on them by the Act of 1886. Though larger than in 1896, the proportion of voters is less than in 1886, when it was 74 per cent. of the voters, and than in 1891, when it was 61·3 per cent. More than a third of the constituency have abstained from voting, which seems to show an indifference to the privilege or a great satisfaction with the "powers that be" in the profession. The fact must be pondered by those who are contemplating large additions to the number of Direct Representatives. They will be expected to explain why so large a proportion of the profession do not care enough for the principle to return a voting paper at the expense of a penny. Parliament does not care to concede votes to those who are not importunate in demanding them and faithful in the use of them when conferred.

A feature of this election was the practical concentration of the votes on two candidates. When the votes are scattered over ten candidates, as they were in the election of last year, the influence of the candidate returned is weakened. The rest of the Council may, if they choose, regard such a Direct Representative as the delegate of a section rather than as the choice of the profession. On this occasion there can be no doubt that Mr. HORSLEY and Sir WALTER FOSTER constituted between them the choice of the profession—or rather of those members of the profession who chose to exercise their prerogative of voting. The votes were practically divided between them, and as their public promises differed in no material way either can, if he likes, claim to represent the medico-political views of his opponent's supporters. In a second respect the recent election has been significant. Hitherto two principles have had considerable sway; firstly, that there should be a rough territorial representation as between the metropolis and the provinces, and secondly that the Direct Representatives should be general practitioners. These principles have been quite ignored. The member whose retirement created the vacancy was a provincial representative. An eminently able provincial physician offered himself for the vacancy, and he has been beaten by a London candidate who received very great provincial support. The other principle, that preference should be given to a general practitioner for a Direct Representative, seeing that the Council consists so predominantly of members of the consulting or teaching class, has been no less neglected. Concerning this point, we are still strongly of opinion that, other things being equal, the seats of direct representation should be filled by men in general practice. But other things must be somewhat equal, and it would have been difficult to find any general practitioner with Mr. HORSLEY'S knowledge of the reforms needed to make the general practitioner's life easier and his remuneration more secure. Certainly no one possessing similar practical experience presented himself on this occasion as a candidate for election. We shall watch Mr. HORSLEY'S career in the Council with the greatest interest. His first official action, as announced in his letter to the profession, which we publish in another column, is full of promise. With distinct self-sacrifice he pledges himself to retire from the Council in 1901, when the term of the other two Direct Representatives for England and Wales expires, thereby saving the profession from the inconvenience and the Council from the expense which would otherwise have been entailed by Dr. RENTOUL'S procedure.

Annotations.

"Ne quid nimis."

ABSENCE OF MEDICAL EVIDENCE AT INQUESTS.

WE have read the reports of two inquests recently held in Gloucester. Inquest number one was on the body of a man, unidentified, which was found in a pond. A police constable deposed to finding the body. He "got it out and removed it to the mortuary, but could find no marks of injury; ..... he believed it had been in the water eight or nine days." An open verdict was returned. Apparently there was no medical evidence called and no attempt to find the cause of death. Inquest number two was held on the body of a girl, aged nineteen years, which was found in the canal on Oct. 4th. The mother deposed to seeing her daughter for the last time on Sept. 29th; she was then perfectly well and cheerful. William Voyce spoke as to the recovery of the body and bringing it to the mortuary, and Emma Maisey said she made an examination, but found no marks whatever on the body or any sign of injury. The coroner said there was no sign of suicide or any evidence to show how the girl got into the water. If the jury were not satisfied he would adjourn the inquiry. The jury thought it unnecessary to adjourn the inquiry and an open verdict of found drowned in the canal was returned. Now we should very much like to know how this jury arrived at the conclusion that the girl was drowned. Is anyone found dead in the water necessarily drowned? The deceased might have been murdered and thrown into the water dead, or drugged and thrown into the water while still alive, or have fallen in accidentally, despite her hat and umbrella having been found on the bank; but what is the use of pursuing further hypotheses? Suffice it to say that if ever there was a case which called for a strict inquiry and medical evidence founded on a post-mortem examination this case is such an one.

SEWER VENTILATION AND TYPHOID FEVER.

A CORRESPONDENT at York sends us a newspaper cutting from which we gather that the question of sewer ventilation has been exercising the minds of the City Council. The city has spent upwards of £200,000 on its system of sewerage and has adopted, under competent advice, the plan of surface ventilators. These have proved less successful than could have been wished; the smells arising from them are stated to be abominable, and during a recent discussion at a meeting of the Streets and Buildings Committee the prevalence of typhoid fever in the city was by certain councillors openly ascribed to this source. Other members of the council, and amongst them a highly qualified medical man, maintained that the escape of sewer gases into the fresh air, though

Digitized by Google

possibly deleterious, was incapable of causing typhoid fever; and it is this statement which has excited our correspondent's ire. The question, as a matter of fact, is one of considerable difficulty. Cases are not wanting in which the escape of sewer air has apparently led to typhoid fever, as in the instance of Eastney barracks, where proper sewer ventilation put a stop to the frequent occurrence of the disease. On the other hand, we have not only the growing evidence that typhoid fever is in the main a water-borne disease, but the fact also that men employed in sewers and sewage works are not specially subject to it. Above all, we have good experimental evidence that sewage does not, under ordinary circumstances, give up the bacteria which it contains to the air in contact with it. The testimony on this point is almost unanimous. Miquel, Carnelly and Haldane, and Laws all find sewer air remarkably free from germs, and the last named, in an investigation carried out for the London County Council, proved that the species of micro-organisms present in the sewer air in London were related to those of the fresh air outside and not at all to those present in the sewage. Not once in numerous experiments did he find the bacillus coli communis in sewer air, though it was shown to teem in the sewage. Thus the balance of evidence goes to show that the conveyance of the typhoid fever germ by sewer air must at least be very exceptional, and we know of no proof that the disease ever arises as the result of the mere escape of sewer gases into the open air. That the inhalation of sewer air may produce injurious effects no one will dispute, but precisely how it does so is at present obscure. It is more than probable that its escape into houses may be a serious predisposing cause of typhoid fever, diphtheria, and other diseases, presumably by leading to general ill-health and thus to a lowering of the powers of resistance against infection borne by other channels. We have only recently pointed out in these columns that the distribution of typhoid fever in Maidstone may be in part explained by the action of such a predisposing cause as the ascent of sewer air into the houses in the higher regions of the town. But certainly the injury is at a minimum where the sewer gases escape into the open air. If the sewers of York give rise to offensive effluvia this may be either that the surface ventilators are not sufficiently numerous or that the sewers have not a fall adequate for their efficient flushing. The experience is pretty general that for large towns surface ventilators are on the whole the best means of ventilating sewers. In London they may be said to work well, and such nuisance as may from time to time locally arise is rather a useful indication of imperfect flushing than a danger to the health of the community.

OVER-PRESSURE IN SWISS SCHOOLS.

EDUCATION itself has not a little to learn, and in the European country where it exceptionally flourishes it is at present conning the self-imposed task contained in the copyline, "Ne quid nimis." "Surmenage," or what we call "over-pressure," is now a recognised evil in Swiss schools, productive, as Sir J. Crichton-Browne and THE LANCET demonstrated in a memorable controversy, of neurasthenia and many other organic ailments, imperfectly summarised under that term. Nearly every canton in the Confederation can point to its cases, more or less numerous and aggravated, of "la neurasthénie scolaire," and the canton of Lucerne, at a recent conference of its "Régents," had under consideration a series of propositions for combating the evil. These were eight in number, and they came before the conference under the high educational authority of Dr. S. Stocker, who is also an expert in school hygiene. The first proposition would limit instruction in primary schools to reading, writing, and arithmetic, drawing ("dessin"), object-lessons pursued by preference in the open air, gymnastics, and singing. These branches should form the work of the six classes recognised in Swiss primary schools, but in such a way that drawing, object-lessons, and physical exercise should predominate in the lower classes. Proposition two would put an end in primary schools to all tasks to be performed at home, while in secondary schools they would be permitted only in a restricted degree. The third proposition would regulate the "passages to be learned by heart," limiting them to those which are "concise in style," and even then requiring them to be moderate in length and to be exacted only from the upper classes. The fourth would interrupt the lessons from half hour to half hour by pauses of ten minutes, and the fifth would entirely suppress "examinations on the work done at the close of the day." Proposition six would in summer and when the heat is great have the lessons conducted every afternoon in the open air, and proposition seven would interpose every six or eight weeks a vacation of one or more weeks in the class work. Finally (proposition eight), attendance at school should not commence till after the child has passed the age of seven. The innovations proposed by Dr. Stocker and the influential party he represents may appear too drastic, or, in other words, too indulgent to the pupil. That they have been recommended at all, however, is a proof of the evil they have to cope with—an evil certainly not lessening in an age of competitive examinations and nowhere tending to assume graver proportions than in the British Isles. Readers of THE LANCET may remember the opposition, neither well-inspired nor always fair, encountered by Sir J. Crichton-Browne and other medical authorities at the hands of officialdom headed by the late Mr. Mundella; but the crusade so energetically promoted, if at first resisted by "those in authority" with more zeal than knowledge, justified itself at length and suggested similar movements on almost identical lines in the New World as well as the Old. The vindication of the wisdom that started it came in steadily and strongly from Continental Europe in particular, and finds its latest exemplar in the nationality which, thanks to Pestalozzi and his adherents, has in many ways led the van in popular instruction.

CHLOROFORM ADMINISTRATION TO CANINE PATIENTS.

THAT dogs die readily under chloroform has been commonly held. Like many popular beliefs it has not only no foundation in fact, but is negatived by such evidence as exists upon the subject. The pariah dogs of India, as was shown in the Reports of the Hyderabad Chloroform Commissions, died rarely, unless the vigilance of the administrator was relaxed from his task. Professor Hobday, of the Royal Veterinary College, who has devoted especial attention to the subject of giving chloroform to dogs, has published statistics of 250 cases of chloroform administration with one death. The casualty was due to the rupture of the portal vein in an obese pug dog whilst it was struggling to free itself from its bonds. This death was probably not directly due to the anæsthetic. The apparatus in 180 cases was one which Professor Hobday devised and which allowed air to be drawn over the surface of the chloroform by the direct aspiration of the animal's breathing. The dogs were of various breeds, ages and sizes, and in all stages of condition, some being pregnant, and all being out-patients, so that no preparation was possible. Vomiting is not mentioned as a complication. The students gave the anæsthetic. The patients were usually anæsthetised in the "abdominal position, being the safest and most convenient for the production of anæsthesia; the patient was afterwards placed as required." One dog proved refractory.

Digitized by Google

and after twelve minutes a more concentrated vapour of chloroform was successfully employed. Three "untoward cases" occurred; two recovered after two minims of Scheele's hydrocyanic acid had been placed on the back of the tongue and artificial respiration had been employed, and the third, which died, was the fat pug referred to above. Professor Hobday regards hydrocyanic acid as antidotal to chloroform and directs the use of a "full medicinal dose" it in respiratory failure. But as artificial respiration is also used it is perhaps not certain what *rôle* the drug plays in the resuscitation. The lateral posture and rapid rhythmic compression of the ribs are the means of artificial respiration recommended, and there is no doubt that in most cases animals with pliant ribs can be rapidly restored by this method even without traction of the tongue, although that is often a valuable aid. The remaining seventy patients were chloroformed by Professor Hobday's other inhaler,[1] which is practically a small Wolff bottle, the animal breathing air which has been pumped over the surface of the chloroform and not as in Junker's apparatus driven through the anæsthetic. Professor Hobday's conclusions are that chloroform is not particularly dangerous to dogs or other animals unless improperly administered in an insufficiently diluted vapour and in an irregular manner.

VIEWING THE BODY.

AT an inquest recently held at Accrington by Mr. F. D. Robinson, the deputy coroner, the jury complained through their foreman of having to view the body and asked if they were compelled to do so by law. Mr. Robinson replied that they were so compelled. The foreman then asked if the coroner was not obliged to view the body also, and received an answer in the negative. It is, of course, the fact that the coroner is not bound by law to view the body, but in our opinion he certainly should do so, above all if he be a medical man, for certain appearances might very well be present which might in that case lead him to conduct his inquiry in some particular way or to adjourn the inquest so as to have a post-mortem examination made. This, in fact, is one one of the great reasons why we have always insisted on the propriety of the coroner being a medical man. The jury finally passed the following resolution, "The jury believe the viewing of dead bodies by juries to be useless, but if the law so directs we believe that the coroner's presence should be necessary." As now carried out the viewing of bodies is certainly rather a perfunctory ceremony, but, to quote the compilers of the Prayer Book, "the abuse of a ceremony doth not take away the lawful use of it."

A FURTHER IMPROVEMENT IN DISINFECTION BY STEAM.

SATISFACTORY as are the results obtained by the use of such apparatus as those of Lyon, Reck, and others, it must be admitted that the air confined in a closed chamber presents an obstacle to the penetration of the interstices of stuffed or packed goods by the superheated vapour which is not met with when "current" steam is employed, though this preliminary loss of time is more than compensated by the greater efficiency of the higher temperatures (from 220° to 240° F.) over the lower (from 170° to 180°), however prolonged. Since, however, the high temperature must be not only reached but maintained for about a quarter of an hour in the interior, it follows that the exterior of an article of clothing or bedding is exposed, more or less to its detriment, twice as long as is really necessary. This objection has now been completely overcome by a contrivance as simple as it is ingenious adopted in the apparatus with which the disinfection steamboat, *James Wadsworth*, engaged in the Port of New York, is provided, and which is described by Dr. Alvah Doty, the health officer of the port, in the August issue of the *American Journal of the Medical Sciences*. It consists in the exhaustion of the air in the chamber so as to produce a partial vacuum before the steam is admitted; and it is found that all other circumstances being alike a temperature of 240°, that of the steam in the chamber, is reached in the interior of a mattress or like article in less than three minutes with the vacuum, though without it from ten to fifteen minutes are required. The *James Wadsworth* oven is constructed with double walls and is encased in a jacketing of asbestos, which so prevents the loss of heat by radiation that the room in which it is fixed is not perceptibly warmer than others in the vessel or building. The special feature, however, is the steam exhaust, which consists simply of a powerful jet of steam coming directly from the boiler, where a pressure of 65 lb. to the square inch is maintained, passing across the mouths of 1½ in. pipes connected with the chamber of the oven, and with the space between its inner and outer walls. A similar pipe communicates between the chamber and the outer air, and the steam is admitted by one of 2½ in. in diameter, furnished with a regulating nozzle by which the pressure may be reduced to 15 lb. or 10 lb., which is sufficient for a temperature of 240° in the chamber. All these pipes are of course provided with stop-valves. The operation, after articles to be disinfected have been introduced and the doors securely closed, is to set the steam exhaust to work until the manometer or steam gauge indicates a pressure in the chamber and surrounding wall space of not more than twenty inches—a partial vacuum which is attained in about one minute. The valves are then closed and the steampipe opened, when the superheated vapour entering under a pressure of two atmospheres into the rarefied atmosphere of the chamber penetrates the densest fabrics and stuffed or packed goods, raising their temperature throughout to its own in three or four minutes. Ten minutes at 240° destroys bacilli of plague and anthrax, however protected, with absolute certainty, so that in fifteen minutes from the commencement of the process the steam may be turned off, when the steam exhaust is again set in action, though on the chamber only, until the former vacuum has been restored; then the air inlet is opened, and the exhaust still acting draws such a powerful current through the chamber that in two or three minutes every trace of moisture has been removed, and wearing apparel may be resumed within less than half an hour of its having been given up, an interval clearly none too long for the bath and cleansing of the persons of the wearers—in this particular instance mostly steerage passengers, immigrants from places where cholera, yellow fever, or other epidemic prevailed, or among whom cases had occurred on the passage.

THE SANITARY OATH.

A CORRESPONDENT writes: "The profession has to thank Mr. Justice Day for the happy phrase—'the sanitary oath'—and does so gratefully, as he thereby acknowledges that the ordinary form of oath is insanitary. I well remember hearing him christen it and the tone of scorn in which he asked if anyone could believe that diseases were contracted by kissing a New Testament. I know of one New Testament that has been in constant use for thirteen years, and what there is left of it is not a pleasant thing to caress. Though the Scotch form of oath has, perhaps, not made such rapid progress as one might wish, it is doubtless steadily coming into favour with those best qualified to judge of its worth. The late Mr. Justice Cave stated in public that he liked to see the oath taken in this way, and last week, when the magistrate's clerk [illegible] had to give evidence in a case of alleg[illegible]

[1] See THE LANCET, July 24th, 1897.

Digitized by Google

this method. The great objection seems to be that the witness has to repeat the words and stand in a more or less constrained attitude, thus making himself very conspicuous. This to a man of a nervous or retiring temperament acts as a deterrent. Again, the time occupied is considerably greater than with the ordinary oath." Our correspondent concludes by asking if it would not be possible for the clerk to repeat the words of the English oath and for the witness to assent to them, not by kissing the book, but by raising the hand. This, we think, is a very good suggestion, but it would be at the present moment illegal.

A NEW OCULIST'S SEAL.

A NEW seal of a Roman oculist has recently been discovered in France, and its inscription may be found in the *Révue Archéologique*. This seal brings the number of known examples of these interesting monuments of medical antiquity up to about 200. The text upon the seal is, "Luxsuri Diasmyrnes post, impetum. Decorati cloron Opobalsamum." As in several other cases, the seal apparently bears the name of two oculists. The first remedy, diasmyrnes, or myrrh, Διὰ σμύρνης, is frequently prescribed on these seals for "post impetum (pituitæ lippitudinis), which Sichel, in reference to a passage of Celsus VI., 6, 1, translates as "after the mucuous secretion of ophthalmia." All the great medical classics, of course, allude to it, as also do Scribonius, Marcellus, and Actuarius. Up to the present it has been found designated as a remedy for post impetum, by itself, upon six of the oculists' seals. Cloron, perhaps from χλωρος, green, is mentioned by Galen and Aetius, and occurs upon a seal found at Kenchester (see Simpson in the *Monthly Journal of Medical Science*, 1851, p. 250). Opobalsamatum, ὀποβάλσαμον, sugar of balm, is upon the seals only stated to be given by itself *ad caliginam* and that on only one seal. It is, however, mentioned upon two others and on a vase without the addition of the name of the malady to which it was applicable. Among other authors it is spoken of by Paulus Aegineta and Nicolas Myrepsus. It is frequently found upon oculists' seals associated with other collyria such as copper and oil of myrrh.

THE TREATMENT OF SEPTICÆMIA.

SEVERAL observations have been published on the treatment of pyæmic affections by means of yeast and its preparations. In the *Medical News* (New York) of Sept. 25th is a paper by Dr. Walter Courtney entitled "Yeast Nucleinic Acid in the Treatment of Septicæmia, with Report of Cases." For the purposes of this article Dr. Courtney defines septicæmia as "a general systemic invasion by one or more varieties of the pyogenic or putrefactive bacteria, their products, or both." Dr. Courtney had observed Dr. Vaughan's experiments with yeast nucleinic acid on rabbits and guinea-pigs which had been inoculated with the bacillus tuberculosis, the bacillus of tetanus, and the bacillus anthracis, and in different animals. The inhibitory and frequently curative effect of the nuclein treatment of these various infections was most marked, and Dr. Courtney subsequently tried it in the treatment of patients suffering from septicæmia. The results, as shown by ten cases published in full, were very satisfactory, only one case proving fatal; but, as Dr. Courtney candidly admits, the auxiliary treatment employed may have had something to do with the results; these aids were those "which effect free elimination by all of the emunctories that may be pressed into service, so as to rid the system of all the toxins possible," especially free purging. Dr. Courtney sums up his experience thus: 1. The yeast nucleinic acid should be given at the earliest possible moment that septic infection is suspected. The physician should not wait for the typical and classic symptoms as given by text-books. Dr. Courtney's observations have led him to believe that if delay is made until rigors, icterus, diarrhœa, delirium or apathy, profuse perspiration, and a foul-smelling and discharging wound are added to an abnormal increase in temperature and pulse-rate, and a restless alertness on the part of the patient, to convince the observer that it is septicæmia that must be dealt with, instead of surgical fever or something else, a serious waste of most valuable time must occur. 2. The nuclein should always, in septicæmia at least, be given hypodermically if possible, in order to secure prompt action of the given dose. If the 1 per cent. solution is used, at least from 30 to 40 minims, undiluted, may be given every three or four hours. If the 5 per cent. solution should be used, from 10 to 15 minims may be given every three or four hours, but ought to be diluted with distilled or at least with sterile water. This is necessary to avoid the local reaction which is sometimes caused when this solution is given undiluted. In Dr. Courtney's experience the 5 per cent. solution is preferable, for one reason at least—it is always stable. The 1 per cent. solution is not stable; it sometimes becomes cloudy and unfit for use. 3. The injection region should be examined daily in order to determine if local reaction can have anything to do with the patient's increased temperature and pulse-rate. If it has it is due to one of two things—either to insufficient dilution of the 5 per cent. nuclein solution or to imperfect preparation of the skin or syringe. In conclusion Dr. Courtney remarks: "The results of my work with yeast nucleinic acid in septicæmia are sufficiently encouraging to justify a feeling of confidence and a continuance of its use."

THE EARTHLY PARADISE.

BY the above title we do not mean the Vale of Kashmir, or Atlantis, or the Armenian Plateau, but we refer to the somewhat prosaic district of Montagu-square. It appears from a case tried before Mr. Curtis Bennett on Oct. 16th that the dwellers in that favoured region have a private Act of their own—namely, 54 George III.—empowering them to bring offenders before the magistrate for annoying people by selling newspapers "and noisily endeavouring to attract attention that they had newspapers for sale." Three boys were charged with this offence, and their respective mothers made to enter into their recognisances in £5 to bring them up for judgment if called upon. Mr. Curtis Bennett's remarks were so much to the point that we give them.

"In giving judgment Mr. Curtis Bennett said there was no doubt that these street cries had become an intolerable nuisance in London. Complaints were continually being made in the daily papers. A Bill for the suppression of these noises was brought in during the last session, but, unfortunately, there was no time for it to pass, and it suffered what was known as the 'massacre of the innocents.' People who wanted to be quiet on Sunday ought not to be troubled with the yells and cries of boys, which went on morning, noon, and night. They (the boys) were the plague and pest of every quiet citizen. Not only were people annoyed in their houses, but even when they went to church their ears were filled with these incessant cries. There was one thing—this case would have the effect of making property in Montagu-square more valuable, because it was only where the inhabitants had a special Act of Parliament that they could put a stop to such an annoyance. The time had come, however, when it must be stopped all over London, for it had gone beyond all endurance, and Sunday, instead of being the quietest day in the week, was becoming the noisiest."

We are glad to see that Mr. Curtis Bennett feels the annoyance. It is more than an annoyance—it has become a perfect curse, not only on Sunday, but on every day. The Strand is well-nigh unbearable from midday until any hour at night. Piccadilly-circus is a perfect bear-garden, and even Bond-street, which used to be one of the pleasantest streets in London, is now invaded by the "winner"

Digitized by Google

yelling fiend. It is quite unnecessary to yell. Many of the newspaper-sellers never do so and why should others? We have been hoping for some time that the London County Council would do something to put an end to the nuisance; the press has taken up the question, and it only remains for the police or the County Council, or Parliament, or all of them, to make London what it should be instead of what it is. Unfortunately, we cannot all live in Montagu-square, but it is only laziness and the hopeless dilatoriness which seems to affect our rulers in every department, except that of raising rates and taxes, which prevent other regions of London from being as well off.

THE NEW ISOLATION HOSPITAL AT OBAN: THE GENEROSITY OF A MEDICAL MAN.

As will be seen from the account given in another column by one of our own correspondents in Scotland, the much frequented Highland health resort of Oban has recently acquired an isolation hospital. As medical journalists we are always interested in hearing that any town is alive to the necessity of availing itself of the provisions of the Public Health Act, and specially so when the town in question is a health resort and also much frequented by holiday makers. But in the case of Oban there is more than this, for the new isolation hospital has been provided by the generosity of a member of our own profession—namely, Dr. McKelvie, a well-known and highly-esteemed practitioner in the neighbourhood. The cost has been about £2000, and, as will be seen from the account given by our correspondent, the building has been erected according to the latest plans and has every appliance for doing the work which will be required of it. In the fight against infectious diseases isolation is all-important, and Dr. McKelvie's munificence will be the cause of making the town of Oban a still more attractive resort than it is at present.

PURPURA HÆMORRHAGICA WITH MULTIPLE INFECTION.

PURPURA, like many other terms, should no longer be regarded as a disease, but as a symptom. It may be found in a number of diseases. Of these the infectious form an important group. The following case, published in the *Montreal Medical Journal*, August, 1897, by Dr. Hamilton and Dr. Yates, is not only of great clinical interest, but a contribution to an ill-understood subject—the etiology of purpura hæmorrhagica. A student, aged twenty-two years, healthy and well developed, noticed an eruption of bright red spots of the size of a pin's head, which began over the left ankle and then became numerous over both lower limbs. Three days afterwards a few spots appeared on the arms and then on the chest. The abdomen remained free until the sixth day. A slight knock on any part induced the appearance of extensive and severe bruising. On the night of the fourth day, not having felt ill yet, he was awakened with coughing and spitting of blood. On the following day he lost large quantities of blood from the nose, mouth, and throat, and felt for the first time weakness, rawness of the throat, and slight pains in the knees. On examination, the spots, which were also present on the face, were found to be hæmorrhages. Here and there were larger purpuric areas varying in size and colour. The conjunctivæ presented a few hæmorrhages. The nose was slowly but constantly bleeding. The lips were of good colour. The gums were not spongy. On the soft palate and left tonsil hæmorrhagic areas were seen. The temperature was 102·8° F., the pulse was 100, and the respirations were 24. The fundi were normal. Cultures of the blood were negative. The red corpuscles were 4,840,000, the white corpuscles 6000, and the hæmoglobin 87 per cent. The patient steadily became worse; the hæmorrhages were persistent and intractable; hæmoptysis, hæmatemesis, hæmaturia, and melæna occurred. The palate became sloughy and the eyelids became œdematous. The temperature ranged from 99° to 104°. Finally he became delirious and died on the twelfth day. A necropsy was made ten hours after death. There were many visceral hæmorrhages. The cardiac vessels contained air and the right auricle was distended with gas. The great vessels contained mixed frothy clots. The liver was emphysematous and floated in water. The bacillus aerogenes capsulatus, the staphylococcus pyogenes aureus, and a small bacillus (which on inoculation proved fatal to a rabbit) were cultivated from the blood and viscera. The clinical picture was thus similar to that of an acute infection; between good health and death there was an interval of only eight days. From the history of the case it is hardly possible that the bacillus aerogenes capsulatus was the primary infection; possibly it was the staphylococcus.

PROJECTED SANITARY IMPROVEMENTS IN NEW YORK CITY.

THE large centres of population in America are, with but few exceptions, far behind those of Europe in so far as sanitary arrangements and municipal government are concerned. Of all the cities of the United States New York is probably the most backward in many of the features that tend toward the preservation of the health and comfort of its citizens. Its tenement buildings and its lodging-houses are among the worst in the world and have been lately characterised by a prominent New York reformer as a disgrace even to America; public baths are conspicuous by their absence, and open spaces and playgrounds are few and far between. This state of affairs is in a large measure due to the apathy and indifference of its inhabitants, but there are very evident signs that public spirit is being aroused and interest awakened in any steps which may be taken to further the well-being of the community at large. The question of public baths will be one of the first to be dealt with when the municipal authorities of Greater New York have been elected. In 1895 a law was passed to the effect that "all cities of the first class should maintain such number of free public baths as the Local Board of Health might deem necessary." This law, however, was permissive, and in New York City at least its provisions have not been executed. In certain sections of New York City, and these the most densely populated, there is a great need of water both for domestic use and for the purpose of washing clothes. The suggestion has been mooted in several American cities that the German system of converting the basements of schools in the poorer districts so that they may be utilised as baths should be followed. This plan has met with much success in Germany, and Boston is about to try the experiment. The difficulties in the way of providing New York City with playgrounds of sufficient size in the lower part of the town are very great owing to the lack of space. Strong efforts are being made to overcome these difficulties, and two admirable small parks have recently been opened in the most crowded parts of the east side. Legislative authority has also been granted to the city to expend a million dollars (£200,000) a year for the purpose of providing and laying out parks and open spaces. Still the parks that have been opened up to the present time, excellent as they are, being for the most part covered with grass on which the children may not go, do not fulfil the object of playgrounds. A decision, too, has lately been arrived at by the mayor's committee on playgrounds and open spaces that no free school shall in future be constructed in New York City without being supplied with an open-air playground. In

Digitized by Google

consequence of the small area of uncovered ground the builders were at their wits' end, until finally the brilliant idea struck one of their number that the roofs of the schools might be utilised for the purpose, and thus the problem is to be solved. For a considerable length of time roof-gardens have been prevalent in all parts of America, but the experiment of aerial playgrounds will be altogether a novel one. Although, as has been already mentioned, the municipality of New York City has done little or nothing as regards the decent housing of the poor private enterprise has stepped in and shown the way. In the heart of the "Bowery," the Whitechapel of New York, there has been lately erected, and will shortly be opened, the most palatial building for the accommodation of the poor man that has ever been constructed in any country. This building is designed to afford sleeping accommodation for upwards of 1500 men and the charge is to be 20 cents nightly. The planning and construction of this lodging-house are due to Mr. Ogden Mills, a well-known philanthropist, and it is to be hoped that his example will be followed by other rich men even if it does not rouse the city itself to efforts in the same direction.

THE EFFECTS OF X RAYS ON THE ANIMAL ORGANISM.

MANY cases have been recorded in which the taking of Roentgen photographs of the living body has been followed by troublesome dermatitis and even by ulceration of the skin, but these lesions are by no means constant, and the exact method of their production is not fully explained. The precautions to be taken for the minimising of this inconvenience in the practical use of the rays were described in a communication made to the Congress of Neurology, Psychiatry, Medical Electricity, and Hypnology, which met at Brussels last September, by Dr. Foveaux de Courmelle, of Paris. He stated that these accidents were not infrequent in radiography, where the contact-breaker of the induction coil was made to vibrate slowly, and the Crookes's tube, being uncovered, gave off both x rays and cathode rays. In radioscopy, on the other hand, the motion of the contact-breaker is very rapid, the current is one of high frequency, and the vacuum tube is wrapped in black cloth which stops the visible or light-producing rays, but presents no obstacle to the x rays; under these circumstances it is known that injury to the skin is unusual, and even after prolonged exposure does not amount to more than superficial desquamation. Moreover, the interposition of an aluminium plate between the Crookes's tube and the patient obviates the accidents which many observers attribute to x rays produced by electrostatic currents or high frequency currents. It would appear that it is only the cathode rays that are injurious, and there is no difficulty in excluding them.

ACUTE PLEURISY A FORM OF TUBERCULOSIS.

THE time-honoured doctrine that exposure to cold alone can produce pleurisy, or, indeed, any internal inflammation, seems to be entirely disproved. That cases of acute pleurisy are often tuberculous has been known for some time; that they are almost invariably so seems now to be proved. Attention was first drawn to the subject by continental writers. In 1890 Dr. Alfred G. Barrs read a paper before the Leeds Medico-Chirurgical Society. As the result of carefully compiled statistics he confirmed the conclusion of Mayor that "the majority of cases of simple idiopathic pleurisy or pleurisy from exposure to cold conceal or reveal a tuberculous process." In 1893, however, Dr. William Osler, in his Shattuck Lecture, which we noticed,[1] concluded that two-thirds of the cases were non-tuberculous. But more delicate tests support the former conclusion. In 1895 Eichhorst published the results of injecting the fluid obtained from cases of serous pleurisy into the peritoneal cavity of guinea-pigs. Two-thirds of the animals developed tuberculosis. The *Boston Medical and Surgical Journal* of Aug. 5th, 1897, contains an important paper by Dr. George G. Sears. On injecting tuberculin in ten cases of acute pleurisy he obtained a reaction—rise of temperature—in nine. He limited the reaction to this by using a very small dose—one milligramme—increased if necessary. His results are nearly identical with those quoted by Netter, where thirteen out of fifteen reacted. The question is of practical importance. Though the prognosis as regards the attack is good there remains the tendency to develop other and more serious forms of tuberculosis. Measures to improve the general health may be of great service.

THE TREATMENT OF HÆMOPHILIA WITH CHLORIDE OF CALCIUM.

PHYSIOLOGISTS have known for some time that lime salts play an essential part in the coagulation of the blood. This suggested to Dr. A. E. Wright the possibility of artificially increasing the power of coagulation. He made some valuable researches and showed that the administration of chloride of calcium caused a considerable increase. He found that in hæmophilia the coagulation time could be reduced about one-half. He therefore suggested the use of this salt in the treatment of hæmophilia and other diseases attended with recurrent hæmorrhages. His conclusions have been fully confirmed by the results, especially in the case of hæmophilia, where they are even brilliant. But the value of the treatment appears still to be but little recognised. The following case, published by Dr. Clifford Perry, and abstracted in a recent number of the *Revue des Sciences Médicales*, is very definite evidence. Severe hæmorrhage followed incision of a dental abscess in a case of hæmophilia. Only after four hours' energetic work, and packing the whole space between the alveolar process and the cheek with gauze saturated with strong solution of perchloride of iron, did the hæmorrhage cease. Later epistaxis and recurrence of hæmorrhage from the wound took place, which ceased when the patient was on the verge of collapse. After six hours alarming hæmorrhage again occurred, which all ordinary means failed to stop. Chloride of calcium was given in doses of 1·30 gramme every four hours. In a few hours the effect was marked; a firm clot formed and the hæmorrhage ceased.

ISOLATION IN SCARLET FEVER.

"I AM quite aware that I am making very startling statements, that deeply-rooted prejudice will both hinder and thwart the inauguration of this plan of treatment, that many will look upon it as absolutely Quixotic, and that it will take a long time to overcome both professional and public sentiment, so dreaded is the very name of scarlet fever. Nevertheless, scientific therapeutic medicine must prevail in the end." Such is the last paragraph of a remarkable article by Mr. Arthur Wiglesworth in our present issue. We fancy that most of our readers will agree with the sentiments expressed therein, although they may take objection to the words "deeply-rooted prejudice." We give the author full credi for having published his method of treatment and thus braved full criticism, but in his paper he states that it was read before the Liverpool Medical Society nearly four years ago, and that "subsequent experience has amply confirmed these views so far as practical observation can demonstrate their truth." Mr. Wiglesworth makes use of some very strongly expressed opinions, and we should be interested to know whether he so impressed any

Digitized by Google

of his hearers at the meeting of the Liverpool Medical Society at which he read this paper that they also had made trial of this method. For instance, one sentence runs: "I contend that it is rather our duty to do all that we can to spread the contraction of this attenuated virus to all the other children in the house, knowing that they will have a mild attack"; and in another place it is maintained that not only is isolation quite unnecessary, but "it is inexpedient." Would Mr. Wiglesworth propose to let the unattacked members of the household associate freely with the neighbours who are uncarbolised? Such propositions are entirely contrary to all accepted notions of the spread of infectious fevers, but as Mr. Wiglesworth has the courage of his opinions we have thought it right to submit his views to the criticism of the profession.

SERUM DIAGNOSIS OF TYPHOID FEVER.

THE diagnosis of typhoid fever has been considerably aided by the process which has become generally known as "Widal's test." The application of an observer's name to a disease, process, or test is not a satisfactory one, as is shown by the numerous terms under which exophthalmic goitre is known; but when one name has once become intimately associated with a disease or test, it makes confusion worse if the name is changed or another added. In the *Edinburgh Medical Journal* for this month a paper appears by Dr. Herbert E. Durham on "Serum Diagnosis," in which the writer points out that "if the name of any investigator is to be attached to the method of using the reaction of the blood serum of patients on appropriate bacilli, it should undoubtedly be that of Professor Max Gruber, of Vienna," who was the first to suggest the method, and who urged others to make observations upon the specific agglutinating power of the blood serum of persons who had passed through attacks of typhoid fever and cholera. Widal in Paris accepted the invitation given by Professor Gruber, published his results, and thus his name became associated with the test. Whilst, therefore, giving to Professor Gruber all due credit for being the first to suggest this method of diagnosis, much confusion would result from substituting his name for that of Widal. The latter has done excellent service in elaborating the test and deserves full recognition for his labours. Many reports are now to hand as regards the value of the test, and the general consensus of opinion seems to be that in this reaction we have a great aid to diagnosis in doubtful cases. Dr. J. C. Da Costa, writing in the *New York Medical Journal* of Aug. 21st, gives the conclusion he has arrived at from the observation of a large number of cases. He found that in more than 90 per cent. of cases of enteric fever a positive reaction may be obtained. In more than 90 per cent. of cases examined from the fourth to the seventh days of the disease inclusive a positive reaction may be obtained. In more than 3 per cent. of diseases other than enteric fever reactions are produced which are indistinguishable from typical typhoid reactions. Positive reactions are occasionally met with in individuals who have had enteric fever some months previously, but who are in good health at the time of the examination. Negative reactions are obtained with the blood of healthy persons who have not had enteric fever recently. Typhoid blood which has been kept in a dried state for eighty-six days will produce a typical reaction. In our present number we publish a paper on this subject by Dr. W. C. Brown, detailing his experience with Widal's reaction in the tropics. Its value in diagnosing between typhoid fever and some forms of malarial fever appears to be great. Dr. Brown also draws attention to the errors that may arise from false clumping and the precautions to be taken against their occurrence.

AT the Royal College of Physicians of London on St. Luke's Day the Moxon medal was awarded to the President, Sir Samuel Wilks, Bart., and the Weber-Parkes prize of 150 guineas and a silver medal to Dr. Arthur Ransome. A similar medal, called the second medal, was awarded to Dr. Peter Paterson, of Glasgow. The Baly medal was awarded to Professor Schäfer, of University College.

THE Morison Lectures of the Royal College of Physicians of Edinburgh will be delivered in the College Hall, 9, Queen-street, Edinburgh, by Dr. Alexander Morison, at 5 P.M., on Nov. 1st, 3rd, and 5th. The subject of the lectures will be "The Anatomy and Physiology of the Nervous Mechanism of the Viscera."

DR. A. T. SCHOFIELD delivered on Monday last, at the Library, Lambeth Palace, by permission of the Archbishop of Canterbury, the first of a series of lectures on Sanitation and Hygiene for the Clergy.

HER MAJESTY THE QUEEN has sent the Lord Mayor a donation of £50 to the fund being raised at the Mansion House for the relief of the sufferers by the epidemic of typhoid fever at Maidstone.

DR. D. C. M'VAIL has been re-appointed by Her Majesty the Queen in Council for another term of five years a member of the General Medical Council.

DR. FREDERICK ST. GEORGE MIVART has been appointed a Medical Inspector of the Local Government Board in place of the late Dr. F. W. Barry.

UNIVERSITY COLLEGE, ABERYSTWITH. — The inaugural address for the session 1897-98 was delivered in the Examination Hall of the University College of Wales, Aberystwith, on Oct. 13th by Professor Henry Sidgwick, LL.D., who took "The Pursuit of Culture as an Ideal" for the subject of his address.

ONE of our own Correspondents in Scotland writes:—"An interesting ceremony was performed in Oban on Monday, when Mr. Patten McDougall of Gallenach, a member of the Local Government Board for Scotland, opened the new isolation hospital for the burgh of Oban. For the last seven years the local authority has adopted the Notification Act, but it possessed no hospital for the reception and isolation of infectious diseases. The parochial board, and latterly the parish council, allowed the local authority the use of the hospital in connexion with the poor house for the reception of cases in emergency; and while this concession has proved a great benefit there were obviously many objections to its continuance longer than could be helped. The local authority three years ago secured four acres of ground upon the hill-side of Glenshellach—in every way a most desirable spot for such a purpose. When, however, the question of expense came to be considered inevitable delays occurred, and there appeared to be a danger of the indefinite postponement of the question, but at this juncture Dr. McKelvie, the senior medical practitioner of Oban, came forward, and in the most generous of terms offered a sufficient sum of money to the local authority to enable them to carry out the project which to-day has been successfully completed. The plans were approved by the Local Government Board for Scotland. The building is constructed upon the pavilion principle. There are four wards and an administrative department, and accommodation can readily be made for twelve patients. Situated some distance from the main buildings is a very complete department for the reception of infected goods and for their thorough disinfection. This department comprises an ambulance wagon room, an infected and disinfecting chamber, washhouse, and laundry. The infected and disinfecting chambers are fitted with a double-doored Washington Lyons steam disinfector, with Alliot and Paton's hot-air vacuum improvements, erected by Manlove, Alliot, and Co., of Nottingham. By this means the Notification Act can now be properly utilised"

JOHN ARDERNE AND HIS TIME.[1]

BY WILLIAM ANDERSON, F.R.C.S. ENG.

WHEN the council of the Medical Society of London honoured me by an invitation to write a paper for the first meeting of the session 1897-98, it appeared to me that we might be interested to pause in the midst of our progress through the closing years of the nineteenth century and transport ourselves for a brief space into the lurid and fitful light of the later middle ages, there to make, or renew, an acquaintance with an ancient and most worthy master of the craft of surgery whom we should all delight to honour.

The name of John Arderne is an unfamiliar one even for surgeons, although numerous manuscript copies of his writings are preserved in the British Museum and at St. John's College, Oxford, and appreciative reference to his work has been made by many high authorities on medical and surgical history—notably, by Dr. Daremberg in his "Histoire des Sciences Médicales," by the late Mr. John Flint South and Mr. D'Arcy Power in "The Craft of Surgery," and by my learned colleague, Dr. J. F. Payne, in the "Dictionary of National Biography." It is to the last-named gentleman that I owe my first introduction, now some years ago, to the subject of my discourse. The time at my disposal will allow only a very imperfect study of the man and the time, but if I am fortunate enough to induce a few of the members to inquire further into a curious page of surgical history my chief object will be achieved.

John Arderne, a contemporary of Chaucer, Wycliffe, Froissart, Petrarch, and Guy de Chauliac, belongs to a period of extreme interest in the evolution of general and surgical literature, and it will be seen that he within his sphere gave no mean aid towards the advance of a higher culture. Of biographical facts we have but little record, but it is known that he was born in 1307[2] and that he practised at Newark in Nottinghamshire from 1349, the year of the plague, until 1370, when, at the age of sixty-three years, he settled in London. Thenceforth he appears to have devoted his days to the publication of his experiences in the form of treatises upon medicine and surgery. It is surmised that he had been previously attached for a time to the English forces during the French wars in the capacity of field surgeon, for there is no doubt that he was well acquainted with France and its language, and that he had an extensive experience in the treatment of wounds; but although he calls himself "Chirurgus inter Medicos" there is nothing to show that he possessed a Master's degree or any formal licence for the exercise of his calling. However this may be, his writings prove that he was a man of clerkly attainments, with a good knowledge of Latin and French, and well read in the available literature of his profession, quoting freely from the works of the mediæval surgeons, the Arabs, and even from the Greeks. That he achieved fame as a surgeon is no less certain. He refers with pardonable pride to a number of distinguished patients whom his ministrations had restored to health, and he is said to have received from the Black Prince a grant of land in Connaught, and with it the right to prefix the noble particle "de" to his name. It is hard to say whether the position of an Irish landlord was more enviable then than now, but the colossal fees he was able to command from his wealthy clients probably rendered him independent of his Hibernian rentals. In his case, as in that of Guy de Chauliac, the literary labours which have preserved his memory were the outcome, and not the cause, of his success, for it was not until he had won an honourable repose that he found leisure to give the world the secrets of his practice. His writings, couched in fair Latin and dealing with nearly the whole of medicine and surgery as they were then known, were noteworthy productions of a reactionary but still illiterate age, and they appear to have been duly valued during the next three centuries, although none received the honours of the press except an abstract translation of an essay on Fistula, which was printed in 1588 by John Read as an appendix to a translation of Franciscus Arceus on Wounds.

To understand the position of Arderne it is necessary to recall something of the time in which he lived. His period was signalised as one of struggle for emancipation from a long-endured state of physical and intellectual bondage; but science was permitted to lag behind, while metaphysics, astrology, and alchemy took the place of solid research. The study of medicine was perhaps more deplorably in the rear of progress than any other branch of learning. For many hundreds of years the preservation of the lore of the Greeks from oblivion was left almost wholly to the Jews and Arabs, until at last the giant Europe, so long torpid, roused enough to stretch its stiffened members, first in Italy, then in France, then in England, but only to doze again and again before sinking into a new century of slumber. When Arderne was in his prime there was but one scientific centre in Europe where any pretence of surgical teaching was maintained. The once famous school of Salerno had already become effete. The Italian revival under William of Saliceto, Theodoric, Lanfrank, Mondini, and others, had given place to the old stagnation against which Bologna had made a valiant fight before sinking into premature decay. Paris, too, after listening to the teaching of Lanfrank and of Henri de Mondeville, had resolutely turned her face to the wall, and Montpellier alone, thanks in part to its geographical position, which brought it within nearer touch of Arab learning, was liberal enough to sanction the cultivation of anatomical and surgical science, not, indeed, within the walls of its university, but in extra-mural classes, in which, amongst others, Guy de Chauliac, the greatest surgical figure of the age, took a leading part. Even this tolerance soon died out, and Montpellier went the way of Salerno, Bologna, and Paris, but not until the work of Guy de Chauliac and John Arderne was ended. In England the age of Chaucer and Wycliffe made no provision whatever for medical progress, and there was no school of anatomy or surgery throughout the land, and no English contributors to the literature of the subjects could be said to exist, if we except such theoretical references as may be found in the works of Gilbertus Anglicanus and John of Gaddesden, written, like all medical treatises of the time, in Latin. It is true that the writings of the Arab physicians, which gave an imperfect sketch of Greek surgery, and those of William of Saliceto, Roger, Theodoric, the Four Masters, Lanfrank, de Mondeville, and after 1363 the masterpiece of compilation, the *Chirurgia Magna* of Guy de Chauliac, were also procurable in Latin guise, but the knowledge to profit by them was rare indeed in the ranks from which the representatives of English surgery were drawn. In the fourteenth century the lot of those of our countrymen who fell in need of surgical ministrations was a sadly precarious one. The art was regarded by the educated physicians then and for centuries later as beneath their dignity. As expressed by our Elizabethan surgeon, John Read, in the doggerel which he and his fellows loved to prefix and append to their professional writings:—

> "Chirurgery moreover is
> abhorred of the Phisition,
> Who doth esteeme it as a thing
> to vile for his profession."

Outside this august and highly conservative body were several classes of practitioners into whose hands surgery was allowed to sink. First of these came the Masters of Surgery—a small body of men, here, as in France, distinct from the Barber surgeons, but scarcely yet banded into the association that somewhat later strove so well to secure a fitting status for their calling. They held no special position in the social scale of the time and appear to have sprung originally from the same level as the barbers, but to have won especial experience and recognition by the exercise of surgery in the wars and civil disturbances of the time, and in certain instances to have gathered some scholastic training. With this group John Arderne is probably to be classed, and another example may perhaps be found in the person of the author of the remarkable anatomical manuscript brought to light two years ago by Dr. Payne.[3] It is these men, few in number, weak in influence though they were, that we must regard as the most honourable representatives of surgery, and there is no doubt that a dozen men of the stamp of Arderne would have changed the whole history of English surgery. Yet the chirurgery of the Master Surgeon was scarcely a handicraft at all, for the hand played little part in it except in the application of ointments and plasters. The Barber surgeon, the bone-setter, and the travelling specialists did the rest.

[1] A paper read before the Medical Society of London on Oct. 11th, 1897.

Digitized by Google

Next to these came the Barber surgeons, who, thanks to the successive decrees of the Popes in the twelfth, thirteenth, and fourteenth centuries against the practice of medicine and surgery by the priesthood, had inherited the manual functions of the erstwhile monkish physicians, and had begun to develop ambitions above the blood-letting and tooth-drawing, which for some mysterious reason had long been attached to their trade. They had not, however, reached or merited any standing of importance, although as early as 1375 they were strong enough in London to appeal successfully to the corporation for the right to summon persons who practised surgery without due qualification. They themselves were little more than uneducated mechanics, to whom the literature of surgery was a closed book. Much experience must indeed have fallen to their lot, but it fell on a barren soil. Their regular practice seems to have been limited to venesections and dentistry, and to the treatment of contusions, wounds, ulcers, and a few other simple affections; but all ailments outside these were blindly attacked or more discreetly left alone. Neither the Master Surgeons nor the Barber surgeons attempted to deal with the whole of surgery. Beyond the mere opening of a vein or an abscess or the extraction of a tooth there were few operations that were held within the scope of orthodox practice. Arderne says that he knew no man in his time "in all England or in lands beyond the sea" who could cure a fistula—he alone did it. Even operations so simple and then so necessary in warfare as the extraction of arrow-heads were often surrounded by absurdly superstitious formalities. The surgeon and patient were to be clean shriven and to say three Paternosters and three Aves in worship of the Trinity; finally, after a Latin adjuration to the arrow, bidding it come out in the name of God, the surgeon's fingers were permitted to attack the actual task, which was supposed to be miraculously facilitated by the tribute to the Celestial powers. Hæmorrhage, except from a vein opened under proper astrological conjunctions, was a terror to the surgeon, upon whom the idea of the ligature had not yet dawned; strangulated hernia and a score of other grave but remediable conditions were left to the merciful hand of death, and many common affections that should have been perfectly within the sphere of the general surgeon, such as fractures, dislocations, stone in the bladder, &c., were abandoned without a struggle to a low class of specialists of whom we may next speak.

The Specialists constitute the third group of surgical practitioners, perhaps outnumbering both the Master Surgeons and Barber surgeons. The whole country was pervaded by a troop of foreign and native bone-setters, lithotomists, herniotomists, oculists, and others, following traditional methods unguided by anatomical knowledge, but sometimes by dint of experience attaining a fair amount of skill and success and living upon an honestly acquired reputation. Most of them, however, travelled from place to place advertising themselves by barefaced methods not even yet quite extinct or inefficacious, often mingling their handicraft with arrant imposture, and ready to shift their quarters with all needful celerity as soon as the results of their operations threatened trouble to themselves. Such men for this reason were popularly known in France as *coureurs*. That they should be permitted to exist and thrive might perhaps be regarded as the greatest indictment of the surgery of the time were it not that the bone-setter, as ignorant and as impudent as his forbears, is still amongst us even in this last decade of the nineteenth century.

Below all of these there was still another class of pretenders to surgery—a motley crew of base empirics of both sexes, without even a pretence to real knowledge, trading upon herbs, ointments, embrocations, pills, amulets, and the like, mainly for use in such ailments as were capable of recovery in defiance of their intervention. It is unnecessary to speak of them further, their name is legion and their methods eternal, but in that day the orthodox was so little remote from the heterodox in science that poor suffering humanity had small chance of escape.

Finally, outside these various practitioners for gain lay the Amateurs, a numerous body, often of gentle birth, and nearly all of the gentler sex, trained by reading or personal instruction in the use of herbs, drugs, and simple dressings, and prepared to act on emergency as nurses or doctors amongst their families, friends, or dependents. Students of Chaucer may find an inkling of the domestic medical lore of the period in the "Nonne Preeste's Tale," and they may recognise that Damoysele Pertelote still survives in the remoter parts of our provinces. There is little doubt that many of these kindly and charitable people did much good in their generation, and knowing what we know of the bulk of their professional rivals we may think the patients who came under their tender ministrations were not always the most unfortunate amongst sufferers in mediæval England.

Such, then, was the state of surgery when John Arderne came upon the scene. Shorn of almost all the dignity and power it had acquired under the Greeks its prospects were of the gloomiest. What Arderne did towards its revival may be seen by a study of his works.

There are no less than 22 Arderne manuscripts in the British Museum in the original Latin or in early English translations, some of course repeating or overlapping others in matter.[4] They treat more or less fully of almost every kind of medical and surgical disease then known, mainly from the clinical aspect, and with abundant directions for treatment, and nearly all are illustrated with drawings of diseases, surgical appliances, medicinal plants, and other things appertaining to the text. Some of the sketches are curious. One, representing John Arderne examining a case of fistula in ano, has been discreetly reproduced (without the patient) in South's "Craft of Surgery"; another shows the astrological relations of the different parts of the body; fistulas, penile sores, acne rosacea, facial tic, and many other conditions are recognisably figured, and one MS. even shows a portrait of a mad dog. There are, however, no anatomical diagrams. The text consists partly of short essays on the treatment of various symptoms and ailments, partly of elaborate dissertations upon certain sections of surgical disease, as fistula in ano, eye diseases, stone in the bladder, and on wounds inflicted by various weapons, closing with descriptive accounts of the drugs and preparations employed by the author, and careful directions for their use. There is little or no reference to fractures and dislocations, and the only operations described in detail are those for fistula in ano and for cutting a stone out of the urethra. Mention is made of a special instrument for crushing a vesical calculus. Avicenna, Haly Abbas, and the French and Italian surgeons are freely quoted, as well as certain of the writings of Hippocrates and Galen, and the learning of the author is frequently shown also by the use of Greek, Arabic, and French expressions. There is no attempt, however, to construct a complete and systematic arrangement of the diseases the mediæval flesh was heir to from crown to toe after the manner of many of the earlier writers. The English translations are all of early date, the most important of the number being attributed to the beginning of the fifteenth century, and hence probably representing as nearly as may be the language that John Arderne himself would have used in his professional discourse. As this is acknowledged to be the most interesting and original section of the author's work, and will soon, I trust, be brought within reach of the profession and public by the Early English Text Society, I propose to speak of it so far as the time at my disposal will allow. I have to express my thanks to Dr. Furnivall for the loan of a complete transcript which has enabled me to study the style and matter more carefully than would otherwise have been possible. The section in question treats of ischio-rectal abscess, of fistula in ano, and other affections of the lower end of the bowel, and of sinuses in connexion with the bones and joints, and is supplemented by a description of the composition and uses of the various preparations employed by the author, and prefaced by some words of counsel to the neophyte who aspires to success in medical practice. The personality of Arderne is perhaps best shown in this quaint preface. It has already been printed *in extenso* in South's "Craft of Surgery," but a few paragraphs may be quoted now. The introduction, entitled "Of the Manner of the Leech,"[5] begins in a spirit of pious humility and charity that reappears constantly in the course of Arderne's writings. The rest is too pithy to need comment.

"First it behoveth him that will profit in this craft that he set God afore evermore in all his works and evermore call meekly with heart and mouth his help, and sometimes visit of his winnings poor men after his might, that they by their prayers may get him grace of the Holy Ghost. And that he

Digitized by Google

be not yfounden temerary or boastful in his sayings or in his deeds. And abstain he him from much speech and most among great men. And answer he slyly [cautiously] to things asked that be be not ytake in his words forsooth if his works be ofttime known, for to discord from his words and his behests he shall be holden more unworthy and he shall blemish his own good fame: wherefore saith a versifyer, '*Vincat opus verbum, minuit jactantia famam*'—'(let) work overcome thy word, for boast lesseneth good lose (reputation).'

"Also be a leech not much laughing nor much playing. And as much as he may without harm flee he the fellowship of knaves and unhonest persons. And be he evermore occupied in things that beholdeth to his craft, either read he, or study he, or write or pray he, for the exercise of books worshippeth a leech. For why, he shall both be holden and he shall be more wise. And above all this it profiteth to him that he be founden evermore sober, for drunkenness destroyeth all virtue and bringeth it to nought, as saith a wise man, '*Ebrietas frangit quicquid sapientia tangit*' (Drunkenness breaketh whatso wisdom toucheth)."

The next counsel is one that cannot even yet be regarded as superfluous: "Scorn he no man, for of that it is said, '*Deridens alios non inderisus abibit*' (he that scorneth other men shall not go unscorned). If there be made speech to him of any leech, neither set he him at nought nor praise him too much, or commend him, but thus may he courteously answer: 'I have not any knowledge of him, but I learned not nor I have not heard of him but good and honest.' And of this shall honour and thankings of each party increase and multiply to him, after this, 'Honour is on the honorant and not on the honoured.'"

Next he becomes more purely worldly and passes on to private counsel not intended for lay ears: "When sick men forsooth or any of their byside [household] cometh to the leech to ask help or counsel of him, be he not to them over few [brief] nor over familiar [homely] but mene [gracious] in bearing after the askings of the persons, to some reverently, to some commonly, for, after wise men, 'overmuch homeliness breedeth despising.'"

"If he will favour to any man's asking make he covenant for his travail and take it beforehand.[6] But advise the leech himself well, that he give no certain answer in any case, but [unless] he see first the sickness and the manner of it, and when he hath seen and assayed it, though it seems to him that the sick may be healed, nevertheless he shall make prognostication to the patient [of] the perils to come if the cure be deferred. And if he see the patient perceive busily the cure then after that the state of the patient asketh (according to the position of the patient) ask he boldly more or less, but ever beware of scarce askings, for over-scarce askings setteth at nought both the market and the thing. Therefore for the cure of fistula in ano, when it is curable, ask he competently of a worthy man and a great. An hundred marks or forty pounds, with robes and fees of an hundred shillings for the term of life by year. Of less men forty pounds or forty marks ask he without fees. And take he not less than a hundred shillings, for never in all my life took I less than an hundred shillings for cure of that sickness. Nevertheless, do another man as him think better and more speedfully."

"And if the patients or their friends or servants ask by how much time he hopeth to heal it, evermore let the leech byhete [state] the double that he supposeth, that is if the leech hope to heal the patient by twenty weeks—that is the common course of the curing—add he so many over, for it is better that the term be lengthened than the cure, for prolongation of the cure giveth cause of despairing to the patients when trust to the leech is most hope of health. And if the patient consider or wonder or ask why that he put him so long a time of curing since that he healed him by the half, answer he that it was for that the patient was strong-hearted and suffered well sharp things, and that he was of good complexion and had able flesh to heal, and feign he other causes pleasable to the patient, for patients of such words are proud and delighted."

"Also dispose a leech him that in clothes and other apparelings he be honest, not likening himself in appareling or bearing to minstrals, but in clothing and bearing (ob)serve he the manner of clerks. For why, it seemeth any discreet man yclad with clerk's clothing for to occupy gentleman's boards. Have the leech also clean hands and well shapen nails and cleansed from all blackness and filth."

"And be he courteous at lords' boards, and displease he not in words or deeds to the guests sitting by. Hear he many things, but speak he but few, for a wise man saith: 'It (be)seemeth more to use the eyes than the tongue.' And in another place, 'If thou had been still thou had been holden a philosopher.' And when he shall speak, be the words short, and as much as he may fair and reasonable and without swaying. Beware that there be never founden double words in his mouth, for if he be founden true in his words few or none shall doubt in his deeds."

"Have also a young leech good proverbs pertaining to his craft in comforting of patients."—Here follow other curious examples of bedside exhortations from Holy Writ, heathen philosophy, and homely proverbs—"Also it speedeth that a leech can talk of good tales and of honest that may make the patients to laugh, as well of the Bible as of other tragedies, and any other things of which it is nought to charge, while that they make or induce a light heart to the patient or sick man."

"Discover never the leech unwarily the counsels of his patients as well of men as of women, nor set not one to another at nought though he have cause; that he be not guilty of counsel, for if a man see ye heed well another man's counsel he will wist better on ye."

"In conclusion, many things, forsooth, well (bene) to be kept of a leech without (besides) these that are said afore, that may not be noted here for over much occupying. But it is not to doubt that if the foresaid be well kept that they shall give a gracious going to the user to the height of worship and of winning, for Cato saith, '*Virtutem primam imputa compescere linguam*' (the first virtue trow you to be to refrain the tongue)."

Passing to the technical chapters of his work we may take first his account of fistula in ano. Every surgeon who reads this attentively will admit that it stands almost alone amongst English surgical writings down to the time of Richard Wiseman as a record of painstaking clinical observation and of practical research after success in treatment. His description is rich in experience and his methods are recited with a remarkable fulness of the kind of detail that only experience can teach. It is true that his operations were identical in principle with those practised by the Greeks, but he had devised appliances which in his hands gave results that we should not be ashamed to claim in our day. There is, indeed, little that we know in this particular item of surgery that he did not know as well or better. I fain would quote some of his crisply written sentences, but it may not be.

Following the section of fistula is a description of cancer of the lower end of the rectum under the name of "bubo in the lure." He not only recognises the nature and fatality of the disease, but sets forth clearly its distinctions from chronic diarrhœa or dysentery and speaks of the injury that may be done by the administration of unsuitable remedies under a wrong diagnosis. Prolapsus ani he describes as a "going out of the lure." His notes upon fistulæ, or sinuses in the fingers, the legs, over the joints, and in other places are more superficially treated, but are still personal observations that appear to owe nothing to tradition. The essay on hæmorrhoids is of a somewhat different kind. Here for the first time he appears as the compiler, conscientiously avowing his indebtedness to the older masters of his craft—to Bernard of Gordon, Richard, Roland, Roger, Gilbertus Anglicanus, Guy de Chauliac (Mayster Guy) "and other expert men whose doctrine he had beholden and seen." This is less happy than his more practical and original writings and is more obscured by the nebulous theories of his predecessors. Nevertheless, his treatment is fairly sound, although he has been unable to shake off some ancient superstitions shared by wiser and less wise men than himself—for example, that the surgeon must not operate about the anus when the moon is in Scorpio, Libra, or Sagittarius, because these signs token the part in question, and that hæmorrhoids and menstruation are provoked by phlebotomy of the internal saphenous vein, while blood-letting from the external saphenous vein has the directly opposite effect; but these and other beliefs were inevitable in an age when the physiological and astronomical dicta of the ancients were accepted like Holy Writ as unassailable by human reason and beyond appeal.

Passing next to the discussion of clysters in constipation our author finds himself again upon the safe foundation of

[6] In another place he says: "And then accord they of covenant, of which covenant all excusations yput aback, take he the half beforehand."

Digitized by Google

an extensive experience, and he displays a faith in his methods capable of moving mountains of obstruction. "Be the leech not negligent nor foolhardy in his working with clysters, for it is a work of a perfect mystery, for the which I have gotten a hundred times great honour with lucre in diverse places. For why? At London when Lombards ofttimes administered clysters in their manner to colic men and other men constipate, I, forsooth, with the aforesaid manner of clystering at the first time, within the space of a furlong or two, I delivered the patient for certain, the Lord being mene." It will be noticed that although he refers somewhat contemptuously to the pretentious quacks that were his rivals, he never condescends to the violent and undignified diatribes in which his Elizabethan successors were wont to indulge under like provocation.

The final section, devoted to the enumeration of the preparations used in surgery, is full of interest. Many of his ingredients, such as arsenic, verdigris, sulphate of iron, alum, &c., were powerful as stimulants, astringents, or antiseptics, and appear to have been used with judgment; and with characteristic honesty he tells of his mistakes as well as of his successes—how, for example, he had caused sloughing of the leg of a patient, with subsequent necrosis of the tibia, by the unwary use of a mixture of sublimed arsenic and orpiment. Another set of applications consist of oily preparations of the petals of roses, violets, and camomile flowers, oil of sweet almonds, and oil of juniper, the uses of which are clearly and simply stated, while other much-lauded drugs, such as woodbine and scabious, have succumbed to changes of fashion like so much of the materia medica of the present century. He, however, avoids the loathsome elements, that so commonly disgrace the formulæ of his and much later times, and there is but one of his prescriptions that shows an element of superstition, the so-called *sanguis veneris*. This for the poor is a compound of Alkanet with olive oil—a safe, simple, and cheap application for wounds and ulcers; but for the wealthy it is made up more expensively with aloes, myrrh, and other drugs, and contains as its most valued ingredient "the blood of a maiden virgin or of a maiden damosel about nineteen or twenty years which was never impregned tho' she be corrupt"—for, adds our cautious author, "virgins cometh now full seldom to twenty years." The blood, too, "must be drawn out in the full of the moon, the moon being in Virgine, and the sun being in Piscibus." Another compound called "oil of Masticus" (Masticus one ounce, thuris albi Alexandriæ half an ounce, ol. rosæ 1lb), of sufficiently simple composition, must be referred to, for its virtues, as set forth in all good faith by Arderne, might give a lesson to the modern advertiser of electric belts or liver pills. "It helps," says he, "to every akying of stomach, joints, shoulders, liver, spleen, helps to man in the ethic in the phtisic, or disposed to the lepra and to the morphœa [morfie] and to old men and consumed. And anointed, it moisteth the skin and removeth and restoreth the flesh consumed, and comforteth the stomach and maketh it to defy chills; it represseth abominations in the stomach, it giveth appetite, it sharpeth the minde, it consumeth all cold passions. Finally, it availeth to whole men and to sick in all necessities." It is strange that with so all-embracing a remedy he did not regard the rest of his pharmacopœia as superfluous.

Of internal medicines there are few, but two of the number depend on opium for their chief effect. One of these is recommended as an anæsthetic, "so that the man shal not feel whatsoever is done to him," and the other had won a reputation of a more sinister kind, "to make a man sleep against his will after the manner of ribalds and browsers in France, that fellowshippeth them by the ways to pilgrims, that they may rob them of their silver when they are asleep."

With these our citations must end. It is difficult at the present time to adjudge John Arderne's claim upon posterity, but when we remember into what low repute the art of surgery had fallen in his day in England, and how honestly and successfully he strove to elevate it by his example and teaching, we can scarcely do him too much honour. His art was not all we now understand as surgery, although he at least revived two of the ancient operations of the Greeks, but he was a true clinical observer and based his treatment on experience and reason rather than on precedent and superstition. He was, moreover, almost the only English surgeon of his century who is known to have combined the actual practice of his calling with a scholastic training sufficient to master the surgical literature then available and to commit his views and results clearly to writing. It would be too much to expect that he should rise entirely above the astrological, humoral, and circulatory myths of his day, but he allowed his theories to influence him far less than his experience, and he stands as a singularly capable surgeon according to his lights and opportunities, holding his craft in due honour, and doing more than any Englishman of his century or of the three following centuries to raise it in the world's esteem. If we compare him with his great French contemporary, Guy de Chauliac, we shall find in both the same straightness of purpose, the same solidity of reasoning, and the same harmless superstitions; but while Guy de Chauliac was a compiler of genius with a remarkable literary method and sense of completeness Arderne was perhaps the better clinical student and the more practical surgeon; but as a writer, although he had considerable power of expression and an amusing aptitude for terse and pointed quotation, he was somewhat lacking in that gift of order which in an over-strained and often misapplied form distinguished the earlier European surgical authors. The Frenchman constructed a surgical text-book that in its way stood far above anything that had preceded it, and guided the whole of Europe for two hundred years; the Englishman left an assemblage of original observations that offered better lessons to his followers than could be drawn from any digest of the writings of his predecessors. It cannot be said that either added any striking facts or principles to the legacy of the Greeks.

Of the man himself his book conveys a vivid picture. It is easy to see him as the leech of courtly and obliging manners, sober in attire and moderate in speech, and endowed with a self-restraint born of self-respect, with a tact that bore him well through the many difficulties that must have beset the thorny path of the chirurgeon in his day, and with a strong common sense that never rose too near the dangerous level of genius; a good man and true, kindly and honest, but shrewd withal, with a quick eye to the main chance and a capacity for raising expediency to the dignity of principle. He was through all a surgeon, a scholar, and a gentleman, and in the records that he bequeathed he stands before us as one whom we, his professional descendants, may accept with pride and veneration as the Father of English Surgery.

PRESENTATIONS TO MEDICAL MEN.—Mr. Richard Turner, M.R.C.S. Eng., L.S.A., on his retirement from the post of medical officer of Her Majesty's Prison at Lewes, Sussex, after upwards of 37 years' service, has been presented with an illuminated address, together with a silver salver, suitably inscribed, by the officers of the prison past and present, and also a silver cigarette case by their wives, in recognition of his unfailing courtesy and kindness at all times freely rendered to themselves and their families.—The members of the Haddo Lodge of the Loyal Order of Ancient Shepherds entertained Dr. Beveridge, their lodge surgeon, to supper in the Waverley Hotel, Aberdeen, on Oct. 2nd, and presented him with an emblem of merit, handsomely framed, as a token of appreciation of his professional services to the Lodge.—Last week certificates and badges were presented to the successful candidates of the St. John Ambulance Class formed by the employés of the East Depôt of the Great Western Railway Company, Bristol. After the distribution Mr. E. H. Warner, M.D., C.M. Edin., was presented by the class with a silver-mounted walking-stick suitably engraved as a recognition of his services as honorary lecturer.—Mr. J. T. J. Morrison, M.B. Cantab., F.R.C.S. Eng., Mr. A. T. Holdsworth, M.D. Brux., M.R.C.S., L.S.A., and Mr. E. C. Bark, L.R.C.P. Lond., M.R.C.S. Eng., have each been the recipient of a silver cigarette case from the members of the ambulance classes of the Birmingham city police force as thank-offerings for their valuable services to the classes.—Mr. F. MacDougall, L.R.C.S., L.R.C.P. Edin., lecturer to the Runcorn Branch of the St. John Ambulance Association, has been presented by the class with a silver inkstand for his instructive ambulance lectures.—On Oct. 13th, at the Memorial Institute, Almondsbury, Gloucestershire, Mr. Robert Cecil Leonard, M.B. Durh., L.R.C.P. Lond., M.R.C.S. Eng., who for the past two years has acted as assistant to Dr. J. W. Irwin, was presented by his friends and patients with an inlaid mahogany bureau, accompanied by a book containing an address and the names of 158 subscribers, on the occasion of his leaving the neighbourhood.

The Lancet Special Commission

ON THE

METROPOLITAN WATER-SUPPLY.

XVII.[1]

NEW RIVER COMPANY.

HISTORY.

THE full style and title of the Company is "The Governor and Company of the New River brought from Chadwell and Amwell to London." A complete history of the New River and of the people and places connected with it would form a large volume. In the present brief sketch we can do no more than mention the more important points connected with the origin of the enterprise, of the difficulties which had to be encountered, and of the chief changes which have taken place since the original design was carried out. No account however brief would be complete if no mention were made of Hugh Myddelton, by whom the original work was supervised if not actually designed. Unfortunately, so much fiction has been mixed up with the facts recorded of this remarkable man that it is not easy to deal so briefly as could be wished with his share of the undertaking, and his relations with the Corporation of London which initiated the scheme and James I. who saved the adventure from ruin by providing money for its completion.

The original project was to supply London with water from two Hertfordshire springs and to conduct the water in an open and tortuous channel to some convenient place near the city. Some writers have curiously exaggerated the greatness of the undertaking, which was a trivial one compared with the engineering feats of the Romans; nor was the idea a new one. Years before the New River was projected Sir Francis Drake, had supplied Plymouth with water from a source seven miles distant from the town by means of a channel twenty-four miles in length. It seems probable that Drake's conduit may have suggested the New River scheme to the London citizens, and led them to get the sanction of Parliament to the project.

In the year 1606 an Act (3 Jac. I., c. 18) was passed to authorise the Corporation of London to bring water from Chadwell and Amwell in Hertfordshire for the supply of the city. It was provided that the necessary land might be taken, but that the owners should receive compensation the amount of which was to be assessed by Commissioners appointed by the Lord Chancellor. The Corporation was to maintain the "cut" or river which they were to make, and the authority over it was to be vested in the Commissioners of Sewers. In the following year, 1607 (4 Jac. I., c. 12), another Act was passed by which the Corporation were enabled to convey the water, if they thought fit, through a brick or stone culvert. The first of these two Bills was strongly opposed and the claims of a Captain Colthurst[2] were considered at some length in the House of Lords. The Corporation of London, however, did nothing to carry into effect the provisions of the two Acts of Parliament which they had obtained. In March, 1609, the Common Council conveyed to Hugh Myddelton the power to carry out the work which they found themselves unable or unwilling to do. This agreement was supplemented by an indenture, dated April 21st, 1609. Myddelton commenced the work as quickly as possible. He had, however, many difficulties to contend with. The owners and occupiers of the land through which the river was to pass gave him no little trouble. It is indeed small matter of wonder that many of them objected to have their land taken, and that the possible evils prophesied as the result of this undertaking were grossly exaggerated.

The Record Office contains a paper entitled "The Effect of a Bill to Repeal the Acts 3 and 4, Jac. I., for bringing the New River into London, &c." The paper consists of the objections classified, and each objection is answered, the objections and answers being written side by side in two parallel columns. It is apparently a careful compilation from a number of documents stating both sides of the question. In a different and bolder hand, not as part of the list of objections and answers, is recorded the fact that at that time Myddelton had expended £3000 on the work in progress. Amongst the objections urged against the making of the river it was stated that the meadows would be turned into bogs, that farms would be cut up into small pieces, and that the river was dangerous to man and beast.[3]

The agitation against the New River attracted much attention in the year 1610; it seemed for a time possible that the scheme might be overturned by Parliament, and a Bill was brought in to repeal the New River Acts. A letter written on May 9th of that year says: "Much ado there is in the House about the work undertaken and far advanced already by Myddelton for the cutting of a river and bringing it to London from ten to twelve miles off through the grounds of many men, who, for their particular interests, so strongly oppose themselves to it that they are like, as it is said, to overthrow it all." The Bill in Parliament was referred to a committee, and on July 16th the report of the sub-committee was given as to the river, which they had inspected. Fortunately for Myddelton, Parliament was prorogued on July 23rd and did not meet again until 1614, by which time the New River was finished. This opposition, however, was not the only difficulty with which Myddelton had to contend. In 1610 there was a rival scheme for supplying London with water from the Lee at Hackney.[4] This must have been an anxious time for Myddelton, for there was great danger that his scheme would fail. He had made the canal as far as Enfield, but he found that he had spent all his money, the expenses of the work having proved considerably more than he expected. It is usually said that he applied to the Corporation of London for a money grant, but there does not seem to be any truth in this statement, which is given on no reliable authority and has been copied from one book to another. Myddelton applied to James I., and the King agreed to grant the necessary money for completing the work, the conditions being that half the business should be his, and that he should pay half the past and future expenses of the work. It will be seen from what has been said that Myddelton displayed great sagacity in invoking the King's aid at this juncture, and from the time at which he became a part owner of the New River the rival scheme gave no more trouble. The terms on which James I. became part owner of the enterprise were by no means unfavourable to Myddelton.[5] In the after-history of the New River it appears that James was of considerable use in supporting the business against competition. The matter was of great importance to the financial success of the undertaking, and we will, therefore, take this opportunity of anticipating events and saying all that is necessary on the subject in this place.

It happened that in the year 1617 some brewers applied to the "City Lands" Committee for the lease of the water-houses at Dowgate, offering to maintain them and supply the conduit with water; they were to have any surplus water for their brewhouse without Cripplegate. Court influence was brought to bear against this scheme. The Lords of the Council opposed it, the reason being that it would interfere with the business of the New River Company. In the year 1634 the Corporation petitioned the Lords of

---

[1] Nos. I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., and XVI. were published in THE LANCET of Feb. 20th and 27th, March 6th, 13th, 20th, and 27th, April 3rd, 17th, and 24th, May 1st, 8th, 15th, 22nd, and 29th, and June 19th and 26th respectively.

[2] Captain Colthurst appears to have claimed the right of making the river. We do not know the exact nature of his claims. The Corporation of London declined to give him leave to do the work, but it seems that his claims had some foundation and that he ultimately received compensation; but no particulars as to the amount are known, and the matter need not be dwelt upon further.

[3] It is not without interest to mention that as a matter of fact the river was almost fatal to James I. on one occasion. He happened to be riding near Theobalds, his favourite country house, with Prince Charles. His horse fell, and he was thrown into the river which was frozen over. He was dragged out by his boots which were alone visible. His Majesty was afterwards pleased to make some remarks with regard to the fencing of the river.

[4] This enterprise was to be carried out by the Chelsea School of Divinity, which had been endowed by James I. The school had received less public support than was expected, and a project was started that the provosts and fellows should enrich the college by forestalling Myddelton's enterprise and supplying London with water on commercial principles.

[5] The King paid half the expenses and was to receive half the profits, but all the management was to remain in the hands of Myddelton, it being specially provided that the King should not interfere in any way with matters of business.

the Council that they might be allowed to bring a water-supply from Roundhead, near Tyburn, into the City. It is stated that the Corporation had spent much money in laying down pipes and that they were then stayed by the King's command, and they therefore asked the Council's leave to petition His Majesty that they might be allowed to finish the work. The desire of the Corporation of London to keep their conduits well supplied with water was a most reasonable and laudable one, and there is no doubt that the only reason which prevented James I. from readily giving his consent was that he did not wish the water business in which he was interested to suffer. The better the supply of water provided by the Corporation the less reason the citizens would have to buy water from the New River.

In carrying out his enterprise Myddelton had very loyal support from the Corporation of the City of London. When in the year 1610, Myddelton asked for an extension of time to carry out the work permission was readily granted. Again, when a Bill was brought in to repeal the New River Acts the Corporation warmly opposed it on the ground that it was for the preservation of the health of the City, and that Myddelton, as the City's deputy, had already expended £3000 on the work. Again in the year 1614 the Corporation granted Myddelton a loan of not less than £3000.[6]

It is not possible here to give a full account of all the changes which have taken place in the New River since it was first constructed to the present day, and we can do no more than briefly describe the original work and mention the alterations which were subsequently made.

Myddelton's general plan in making the conduit was that advantage should be taken of the lie of the land so as to diminish the engineering difficulties to a minimum. The consequence was that the course of the New River from Chadwell to Clerkenwell was very much longer than the direct distance between those places. As a crow flies, the distance from Chadwell to Clerkenwell is about twenty miles. The course of the New River as originally constructed was over thirty-eight miles. It was not possible, however, to conduct the water the whole way simply by digging a course for it. More than one valley had to be crossed. As Stowe said, in some places "it required a sprightful art again to mount it over a valley in a trough between a couple of hills, and the trough all the while borne up by wooden arches some of them fixed under the ground very deep and rising in height above 23 ft." One of these aqueducts was at Bush Hill near Edmonton. Its length was 660 ft., and it was 5 ft. wide and 5 ft. deep. A similar aqueduct was made near Islington. This was 460 ft. long and 17 ft. above ground. It was called the boarded river, and many pictures of it are still in existence. It remained till after the middle of the last century and was removed during the years 1776–78, when an embankment was made to take its place. The Bush Hill aqueduct was similarly replaced by an embankment during the years 1784–85.

The completion of Myddelton's work was very gaily celebrated on Michaelmas Day, 1613, a day on which it happened that his brother Sir Thomas Myddelton was elected Lord Mayor of London for the next term of office. There was a pageant in which sixty labourers carrying their tools took part, the Lord Mayor, Aldermen, and "a worthy company beside" were present, a long speech was given in praise of the work of Myddelton and of the King, and the flood gates were thrown open and the water flowed into the reservoir at Clerkenwell. From this reservoir the water was supplied to the houses through wooden pipes.

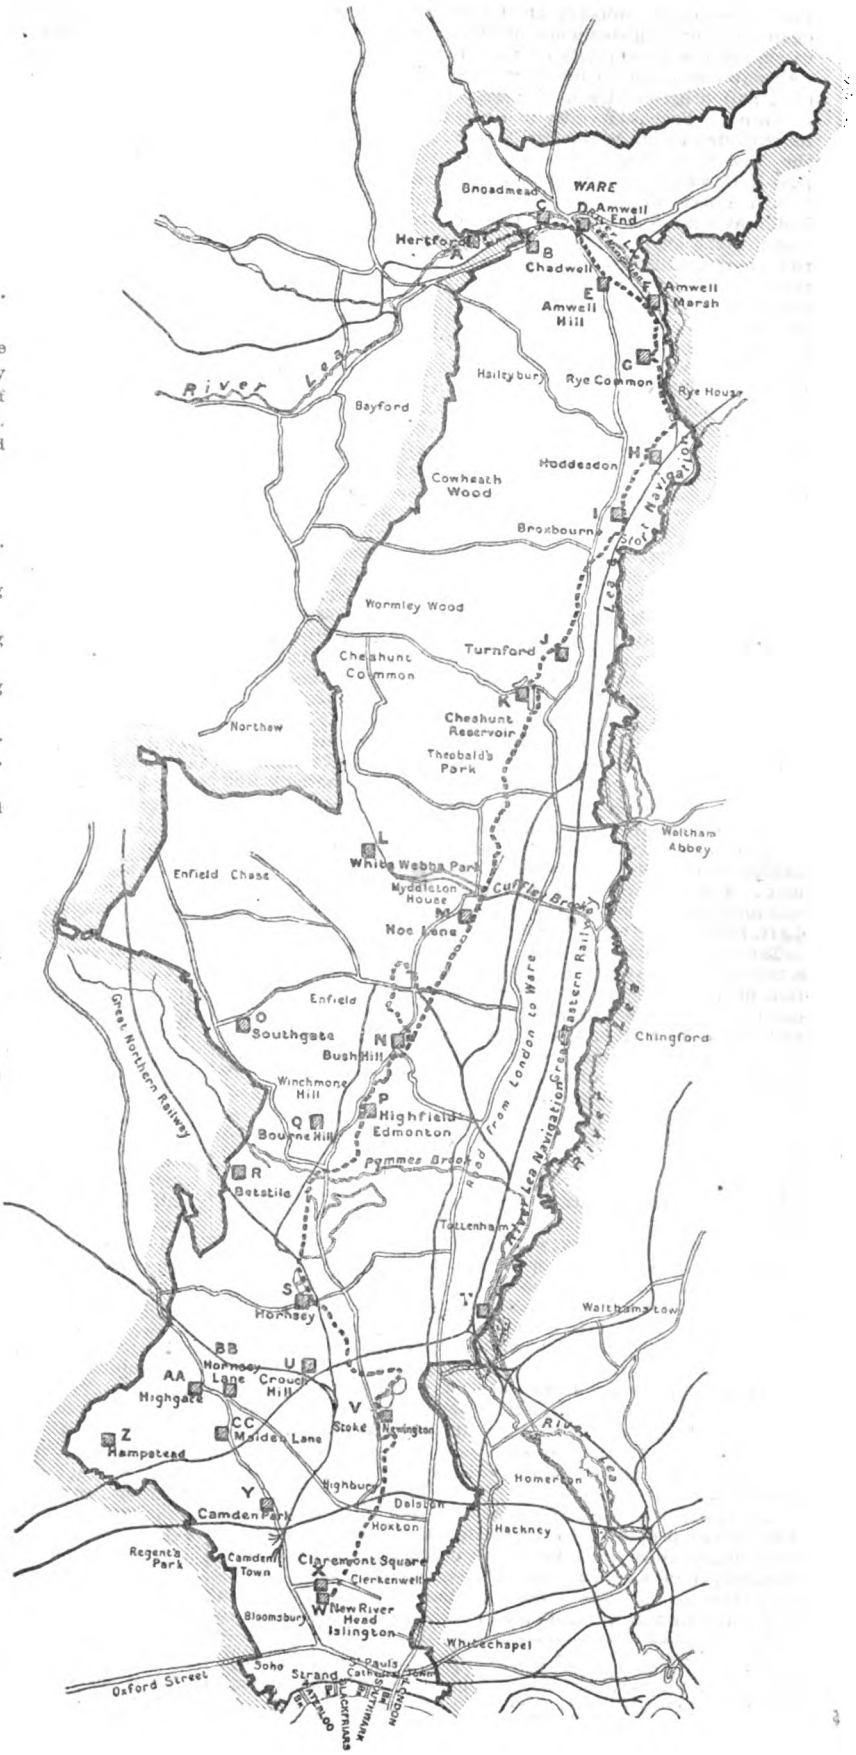
In June, 1619, James I. granted a charter of incorporation and Myddelton was appointed the first governor of the newly constituted Corporation. Several attempts were afterwards made to get Parliamentary sanction to the provisions of the charter, but these were not successful.

During the early part of its career the undertaking was not a financial success. The citizens of London resented having to pay for their water. As time went on the supply to the public conduits belonging to the City became more and more inadequate, and the fittings belonging to the Corporation were greatly injured by the fire of 1666. As the customers of the New River Company increased in number it was found that the springs were insufficient to supply the amount of water necessary, and the Company therefore took some from the River Lee, which flowed near their original source of supply. Complaints were made with regard to this, and some lawsuits followed. In the year 1738 an Act of Parliament (12 Geo. II., cap. 32) authorised the Company to take water from the Lee on certain conditions, amongst which were that an annual payment should be made and that the money should be employed for the improvement of the navigation of the Lee. The amount of water to be taken was to be regulated, and a balance-engine and gauge were erected for this purpose. Later, the Company were allowed to use a gauge made of wood, bricks, or stone on condition that the size remained constant. A gauge of marble was afterwards erected. During the early part of its career the New River Company obtained a good deal of water between Chadwell and London. This was chiefly surface water. Of late years, however, the surface water has been carefully excluded, and many channels have been made to intercept it and convey it into the River Lee below the intake of the Company.

The original intake of water from the Lee was near Hertford, but some years later water was also taken at Tottenham and pumped to Newington. This source of supply has, however, been given up. The pumping station will afterwards be described amongst the disused ones. We may here remark that of late years a number of new wells have been sunk in the chalk and that these supply water of a quality greatly differing from that of the Lee at Tottenham.

During the present century great changes have occurred in the demands of the public with regard to the height to which water should be supplied in dwelling houses, and these demands have necessitated great changes in the manner of the distribution of water by the Company. The reservoirs at Clerkenwell are 84½ ft. above the high water level of the Thames, and this height was sufficient to supply the lower stories of houses. About the year 1810 the public generally demanded higher service, and complaints as to the deficiency of pressure became frequent. For the supply of the western part of London a windmill was used for pumping, but this, as an old writer points out, was not always satisfactory "because of the uncertainty and irregularity of its impelling cause." A horse-engine succeeded the windmill and this in its turn was superseded by a steam engine put up by Boulton and Watt in the year 1787. The services rendered by Boulton and Watt with regard to water-supply were considerable, and amongst other things we have to thank them for the approximately accurate knowledge we possess of the amount of water which was supplied from the date at which their engines were first used. When Boulton and Watt put up an engine one of their conditions was that they should "derive a pecuniary advantage from the saving effected by their means in the expense of coal employed for generating the steam." They therefore put up a machine for registering the number of strokes, and it is from these registrations that the first approximately accurate figures are obtained with regard to the amount of water supplied. A register kept from the years 1787–1788 records that during each of these years the amount of water pumped by the New River Company was over 4,500,000 hogsheads yearly. At this time in addition to the steam power a water wheel was used for pumping the water to Islington. In the early part of the century the supply of the New River Company water was given as far westwards as Marylebone, but owing to the severe competition of the West Middlesex and of the Grand Junction Companies the western supply was afterwards discontinued. At one time the New River Company had about 400 miles of wooden pipes through the streets, but in consequence of the public demand for high service, which necessitated increased pressure in the mains, the wooden pipes had to be given up. Iron pipes were put down between the years 1810 and 1820.

Nelson, the historian of Islington, gives some interesting information as to the water-supply of the district in which he was interested. He says that during the latter half of the last century a large part of Islington was not directly supplied by the New River Company. The inhabitants had to buy their water from people who carried it round and sold it at a halfpenny a pail. At the beginning of the present century the inhabitants of Holloway obtained their water from a cart which brought it from the New River, the purveyor obtaining it from a pump at a place called



[6] This money does not appear to have been repaid until the year 1634, after Myddelton's death. The Common Council, when the loan was repaid, remitted no less than £1000 to Myddelton's widow on the ground that losses had been incurred by him through breaches made in the water pipes when they were broken up for putting out fires. But a great many years afterwards also the Corporation of London made grants to Myddelton's descendants. These grants have been made as recently as the present century.

THE NEW RIVER COMPANY.

The part enclosed within the shaded line includes the whole of the area supplied by the New River Company. The course of the New River is shown by a dotted line. The places marked on the map by shaded squares are—

A, Intake from River Lee near Hertford.
B, Chadwell Spring.
C, Broadmead Well and Pumping Station.
D, Amwell End Well.
E, Amwell Hill Well and Pumping Station.
F, Amwell Marsh Well and Pumping Station.
G, Rye Common Well and Pumping Station.
H, Hoddesdon Well and Pumping Station.
I, Broxbourne Well and Pumping Station.
J, Turnford Well and Pumping Station.
K, Cheshunt Well, Reservoirs, and Pumping Station.
L, White Webbs Well.
M, Hoe-lane Well and Pumping Station.
N, Bush Hill Reservoir.
O, Southgate Reservoir.
P, Highfield (Edmonton) Well and Pumping Station.
Q, Bourne Hill Reservoir.
R, Betstile Well and Pumping Station.
S, Hornsey Reservoir, Filter Beds, and Pumping Station; also Campsbourne Well and Pumping Station.
T, Tottenham Pumping Station.
U, Crouch Hill Reservoirs.
V, Stoke Newington: Reservoirs, Filter Beds, and Pumping Stations.
W, New River Head: Reservoir, Filter Beds, and Pumping Station.
X, Claremont-square Reservoir.
Y, Camden Park-road Reservoir.
Z, Hampstead Reservoir.
A A, Highgate Reservoir.
B B, Hornsey-lane Reservoir.
C C, Maiden-lane Reservoir.

Hopping Lane. In the year 1809 a man named George Pocock, who had property at Holloway, dug a well 172 ft. deep and put up a steam engine and machinery for pumping to supply the inhabitants of the district with water. The well water was said to be of "the finest quality, extremely soft, and consequently fit for washing and every culinary purpose." Pocock formed a small company, which was incorporated by an Act of Parliament (50 Geo. III.).[7] When the New River Company found that the Bill was likely to pass Nelson says that they put down pipes through Islington "with great expedition for the purpose of supplying Holloway with water which was hitherto withheld, notwithstanding the many applications that had for years been made to them and which the inhabitants were now about to obtain through the exertions of an individual." Nelson goes on to say that the Company pulled up a pump from which the Holloway people had been accustomed to get their water "in order to oblige them if possible to have the Company's pipes laid into their premises" He adds, however, that "the housekeepers in the neighbourhood very properly refused to receive water from the New River, and are now for the most part supplied from the well of Mr. Pocock." Mr. Pocock's adventure, however, proved but a short-lived success and soon succumbed to its older rival. In this respect the fate of the little company was identical with that of many other similar enterprises of which a few words may here be said.

Among the undertakings that were bought at various times by the New River Company may be mentioned the London Bridge Waterworks, the Hampstead Waterworks, the York Buildings Waterworks, the North Middlesex Waterworks, and a private enterprise at Bush Hill Park, near Enfield. It is not necessary to enter fully into a description of these adventures. Some account has already been given of the London Bridge Waterworks, and with reference to this part of the subject, it need only be added that when the New River Company took over the business of the London Bridge Waterworks Company it was provided that they should keep up an engine for the purpose of pumping water from the Thames should it be necessary to supplement the supply from the New River in seasons of drought. For this purpose after the destruction of the works on London Bridge, an engine situated at Broken Wharf[8] was for a time used. The engine was of 100 horse-power, and the water was taken from the Thames at a distance of from 30 ft. to 40 ft. beyond low water level.

The northern part of London was supplied with water by a company of adventurers, who obtained from the Corporation of London some of the water rights which had been conferred upon them by an Act of Parliament passed in the year 1543-44 (35 Hen. VIII., cap. 10). This was the earliest Act of Parliament which bore on the London water-supply. By it the Corporation of London were allowed to obtain water from springs at Hampstead Heath, Marylebone, Hackney, and Muswell Hill. The Act authorised the Corporation to enter private lands and search for springs. They were not to interfere with houses, gardens, orchards, or places enclosed with brick or mud walls; but apart from this restriction they were allowed to make ditches and trenches and to lay pipes, and the servants of the Corporation had power to repair the works necessary to convey the water without interruption from the owners of the property from or through which the water was taken, it being only provided that compensation should be paid for damage actually done. In the year 1692 a company of adventurers took over these powers from the Corporation and afterwards made ponds and reservoirs at Hampstead, which were filled by surface water. For some years during the early part of last century the company supplied water over a considerable area, but as the population increased the sources proved insufficient As late, however, as the year 1813 water was supplied to parts of Tottenham-court-road. The area of supply which the company nominally possessed was a large one

The Hampstead Water Company had much trouble with the Hampstead people as to water rights. The ponds are said to have existed in the seventeenth century; the upper pond, however, was smaller than it is at present and covered only three roods. The lower pond had an area of between one and two acres. The Vale of Health Pond was made in 1777. The ponds were fatal, it is said, to many incautious bathers, and there were constant conflicts between the Hampstead people and the water company.

Of the York Buildings Waterworks some account has already been given. The company was finally ruined by the competition of the Chelsea, West Middlesex, and New River Companies, all of which supplied the area in which they were interested. For a time the richer companies reduced their water rates to such an extent that the York Buildings Waterworks were unable to keep their customers. The New River Company then bought up the plant and property of the company.

The water supplied to Bush Hill Park, Edmonton, was put up for the supply of a building estate that was laid out there. A well was sunk, a tower built, and a reservoir made. This business was taken over by the New River Company.

The North Middlesex Waterworks Company carried on business at Betstile, where they sank a well and put up pumping apparatus. This business was taken over by the New River Company.

It would serve no useful purpose to record all the changes which have been made in the course of the New River. The original length of the stream has been considerably shortened and in many places the water is now conducted in pipes, in some the river runs on embankments. The most important improvements which have been made within recent years are that surface water has been as far as possible excluded from the river[9] and that a large number of wells have been sunk to supply the required quantity of water.

GENERAL DESCRIPTION.

The New River Company is the most ancient of all the companies which at present supply London with water. It differs from all the other companies in the fact that it possesses a large quantity of land, and is, as a matter of fact, a land company as well as a water company. With this aspect of the Company this article does not deal, except in so far as the possession of rights affects matters concerning water-supply.

Roughly speaking, the Company supplies the City of London, central London, and the northern suburbs. The area of supply is bounded on the eastern side by the district of the East London Waterworks Company and the district of the Tottenham local board, its southern boundary is the Thames, and on the east the area is bounded by the district supplied by the Chelsea, the Grand Junction, and the West Middlesex Water Companies. The places skirting the northern bank of the Thames are supplied from Charing-cross to the Tower. The most important places supplied are the City of London, Soho, Bloomsbury, Camden Town, Clerkenwell, Hoxton, Kentish Town, Islington, Dalston, Hampstead, Highgate, Holloway, Hornsey, Stoke Newington, Muswell Hill, Betstile, Southgate, and Edmonton.

The water is derived from the River Lee, from Chadwell spring, and from wells at Broadmead, Amwell, Amwell Hill, Amwell Marsh, Rye Common, Hoddesden, Broxbourne, Turnford, Hoe-lane, Highfield, Betstile, and Hornsey, and from ponds at Hampstead and Highgate. The water from the ponds is not used for domestic purposes. The water taken from the River Lee is conducted down an artificial cut, is augmented by that derived from Chadwell Spring and by that pumped from wells situated near the banks of the New River. Of this water, some is filtered at Hornsey and pumped thence into the district around; some passes on to Stoke Newington, where it is allowed to subside in large reservoirs, and is then filtered and pumped to the surrounding district. Some of the water passes on down the New River to New River Head, where it is filtered and pumped to the southern district, including the City of London. Small districts at Betstile and at Amwell Hill are supplied with pure unfiltered well water.

The stations of the Company which are now in working order and which are all marked on the accompanying map are: Intake from the River Lee, near Hertford (A); Chadwell Spring (B); Broadmead, well and pumping station (C); Amwell End, well and pumping station (D); Amwell Hill, well and pumping station (E); Amwell Marsh, well and pumping station (F); Rye Common, well and pumping station (G); Hoddesden, well and pumping station (H); Broxbourne, well and pumping station (I); Turnford, well

[7] An Act for supplying with water Upper and Lower Holloway, Highbury, Canonbury, Upper Islington, and their respective vicinities, all in the parish of St. Mary, Islington, in the county of Middlesex and for other purposes relating thereto.

[8] Broken Wharf was situated between Blackfriars and Southwark bridges.

[9] A former engineer to the Company estimated that at one time something like half the amount of water which fed the river was surface water which flowed into the stream between Chadwell and London.

Digitized by Google

and pumping station (J); Hoe-lane, well and pumping station (M); Bush Hill, reservoir (N); Southgate, reservoir (O); Highfield (Edmonton), well and pumping station (P); Bourne Hill, reservoir (Q); Betstile, well and pumping station (R); Hornsey, reservoirs, filter beds, and pumping station, and Campsbourne, well and pumping station (S); Crouch Hill, reservoirs (U); Stoke Newington, reservoirs, filter beds, and pumping station (V); New River Head, Islington, reservoir, filter beds, and pumping station (W); Claremont-square, Islington, reservoir (X); Camden Park-road, reservoir (Y); Hampstead, reservoir (Z); Highgate, reservoir (A A); Hornsey-lane, reservoir (B B); and Maiden-lane, reservoir (C C).

In addition to these stations, all of which are now in use, the following two disused stations are marked on the map. Cheshunt, well, reservoirs, and pumping station (dismantled) (K); and Tottenham, pumping station (T).

A new well is being sunk at White Webbs (see L on map). In the succeeding articles the descriptions will be arranged in the following order: 1. Survey of the New River, commencing at the intake from the River Lee. 2. The wells, pumping stations, and reservoirs. 3. The pond water (for non-domestic supply). 4. Area of distribution and general statistics.

(To be continued.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY MEETING of the Council was held on Oct. 14th, Sir WILLIAM MACCORMAC, Bart., the President, being in the chair.

Mr. Victor G. Plarr was introduced and signed the usual declaration on his admission as Librarian.

Mr. C. H. Golding-Bird was admitted a member of the Court of Examiners.

The best thanks of the Council were given to Mrs. Gowland for her presentation to the College of drawings by the late Mr. P. Y. Gowland, F.R.C.S. Eng.

It was resolved that the picture of Henry VIII granting the Charter to the Barbers and Surgeons should be restored.

In accordance with the recommendation of the Committee of Management the following institutions were added to the list of recognised places of instruction in chemistry, physics, and practical chemistry: The Staffordshire County Technical Schools; the Devonport Municipal Science, Art, and Technical Schools; the Salford Royal Technical Institute; the Hull Municipal Technical School; the Higher Grade Board School, Norwich; the Bury Technical School; the Southport Victoria Science and Art School; the Maidstone Municipal Technical School; and the East London Technical College, People's Palace.

Mr. Thomas Bryant was re-elected a member of the Committee of Management, and Sir William MacCormac and Mr. Henry Morris were elected members of the Laboratories Committee.

The Laboratories Committee reported that since June 4th the director, Dr. Sims Woodhead, had supplied 9825 doses of antitoxic serum for the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board, each dose contained 2000 units.

Dr. Woodhead also reported the results of a recent visit to Germany in order to compare his methods of preparation of diphtheria antitoxin with those in use in that country.

"On my arrival in Berlin," he wrote, "I went to see Professor Ehrlich, who at once said that he would do everything in his power to help me in obtaining information and making experiments. My first object was to obtain as exact a comparison as possible between our results in serum-testing and those made by Professor Ehrlich and Dr. Dönitz, as the reliability of all our earlier experiments depended essentially on a comparison between two such sets of results. Dr. Dönitz first made a series of experiments, so that I was able to follow exactly the methods of dilution and of administration used at the testing station. At the same time I carried out a series of dilutions according to the methods used in our laboratories. From day to day the reactions obtained in the different animals injected by Dr. Dönitz were carefully examined and noted, and the several experiments were compared. I then obtained from Professor Ehrlich and Dr. Dönitz records of a series of experiments carried out upon the serum sent to Professor Ehrlich from our laboratories. The results obtained were compared with those obtained by us in our earlier experiments: and it appeared that our readings, obtained by the old method, differ to the extent of only about 5 per cent. from those obtained by the new method. Professor Ehrlich then expressed the opinion that the serum he had thus examined for us was equal to any that is in the market. He also informs me that he has tested a number of the other serums examined by us, and that he had obtained results very comparable with ours, and that we could therefore rely upon our figures as being relatively and, within certain limits, actually correct. Professor Ehrlich also stated that, speaking generally, our methods and results were thoroughly reliable. In this he was corroborated by Dr. Dönitz, and later by Dr. Libbertz, of Höchst. They were also greatly interested in the new method of preparing serum, and all of them have determined to try it, as they say that it will be a great improvement if it will work as well as it seems to do here. I have been requested to ask Dr. Wood to send pamphlets to Dr. Libbertz and Dr. Aronsen. Concerning the method of collecting samples of serum, the modes of sealing and controlling, the price of testing the serum, I have obtained all necessary particulars. In every case six samples are taken from large bottles containing several litres. These and the stock flask are then placed under seal, and are sent to the laboratory. One of these samples is examined immediately; the others are put aside for future reference. The samples are tested, first, as to the presence or absence of micro-organisms; secondly, for the quantity of preservative material that has been added; and thirdly, for the number of units in each c.c. of the sample. These tests are always made in duplicate. When these duplicate experiments do not accord, a final determining experiment is made. If the strength of the serum does not come up to the required standard, it is simply returned as being below what is claimed. A fixed fee is taken for every fresh testing of these returned samples. The new method of testing the serum with large quantities of toxin is that now always used, as it is sufficiently delicate to measure to within 1 per cent. Professor Ehrlich maintains, however, that the old method in capable hands also gives exceedingly good results, probably to within from 5 to 10 per cent. He recommends, however, in all cases that an allowance for such proportion of error and for fall in the antitoxin strength of the serum should always be made."

The Chairman of the Annual Report Committee presented a draft copy of the report to be presented to the Fellows and Members at the annual meeting to be held on Nov. 18th, 1897, at 3 P.M.; it was approved.

Mr. R. J. Godlee was elected a member of the Court of Examiners' section of the Board of Examiners in Dental Surgery in the vacancy occasioned by the retirement of Sir William MacCormac.

A vote of thanks was given to the President and Mr. Jessop for representing the College at the Moscow Congress.

The President reported that he had accepted on behalf of the Council a portrait of Frère Jaques, presented to the College by Mr. Sharon Grote Turner, to whom the best thanks of the Council were accorded.

A letter was read from the Parliamentary Bills Committee of the British Medical Association expressing the hope that the President, with one or more members of the Council, would join a deputation to the Secretary for War on the subject of the Army Medical Service, and enclosing copies of a report of a sub-committee on the question of advancing army medical reform. The matter was postponed to the next meeting, but copies of the report mentioned were ordered to be sent to each member of the Council.

A memorial was read signed by medical practitioners resident in Great Yarmouth, calling attention to certain facts in connexion with medical aid associations and submitting the following questions for the consideration of the Council—viz.:

(*a*) Is the holding of appointments such as are herein described compatible with the conditions under which your diploma is granted and held?

(*b*) If the holding of such appointments by your diplomates does not contravene the existing regulations does not your Council consider that, in the interests of the medical profession and of the public, by-laws forbidding such practice should be adopted?

(*c*) Is not your Council of opinion that for a medical man to hold such appointments should be declared by the General Medical Council to be conduct infamous in a professional respect; and, if so, will your Council instruct its representative on the General Medical Council to support such a declaration?

The following reply was directed to be sent:—

"That the memorialists be informed that there is no provision in the Charters or By-laws of the College prohibiting Fellows and Members of the College from acting as medical officers to medical aid associations, but that the Council, while not prepared to express an abstract opinion on the questions raised, are willing to consider any evidence which may be submitted to them respecting canvassing for patients, either directly or indirectly, by any individual Fellow or Member of the College, with a view to determining whether or not such Fellow or Member has been guilty of a breach of the By-laws."

BORACIC ACID IN BUTTER.—At Barry Police-court on Oct. 11th a local tradesman was fined twenty shillings and costs for selling butter which contained an excessive quantity of boracic acid. The public analyst certified that the butter contained 9 per cent. of boracic acid. Dr. Williams said he considered the amount of boracic acid to be four times the quantity required to preserve butter when no salt was used. The butter, he added, contained 60 grains to the pound, and this would be highly injurious if taken for any length of time.

THE ELECTION OF A DIRECT REPRESENTATIVE.

As we were able to announce last week, Mr. Victor Horsley has proved the successful candidate for the vacancy caused by the resignation of Dr. Rentoul of his seat as a Direct Representative of the profession for England and Wales. The Branch Council certified on Saturday last the result of the election, and the exact number of votes polled by each candidate proves to have been as follows:

MR. VICTOR HORSLEY	6946
SIR WALTER FOSTER	6112
DR. RIGBY	197
DR. DIVER	81

Mr. Horsley was thus elected by a majority of 834 votes over Sir Walter Foster.

The number of voting-papers sent out was 22 576 (the additions to, and removals from, the Register having so counterbalanced each other as to bring the total within one of the number sent out in 1896). Of these, 13 466 (or 59·64 per cent.) were returned by the voters within the proper time according to the regulations; 227 (or 1·01 per cent.) were returned by the voters, but received at too late a date to be lawfully reckoned in the enumeration; 822 (or 3·64 per cent) were returned through the Dead Letter Office; and 8061 (or 35 71 per cent.) did not come back in any way—total, 22 576.

The percentage of voters on the present occasion was 5·42 greater than in 1896—59·64 per cent. in 1897, as against 54·2 per cent. in 1896.

Of the 13,466 voting papers duly returned, 130 (or 0 9 per cent) were invalid owing to the following various causes: 4 were entirely blank; 11 were signed, but not marked; 82 had no signatures; 28 were improperly marked: 3 practitioners to whom voting papers were sent were stated to be dead; and 2 voters were stated to have gone to the colonies—total, 130.

It may be noticed in this connexion that, although there was but one member to be elected, in two cases the voters selected two candidates, and in two other cases voted for three candidates.

We have been requested to publish the following letters of thanks from Mr. Victor Horsley, Sir Walter Foster, and Dr. Diver:—

To the Registered Medical Practitioners of England and Wales.

LADIES AND GENTLEMEN,—I beg to thank you sincerely for the honour you have conferred upon me by electing me as one of your Direct Representatives on the General Medical Council.

In the confidence thus extended to me I fully recognise that you have desired to give expression to your approval of the reforms initiated, and already in part effected, by the Medical Defence Union and your wish to see them extended and furthered by the same methods. If it should prove that I am able to carry out your wishes in this respect any success achieved will be due to the council and members of that union, as it is to their support, assistance, and teaching that I owe the training for the work you have decided to place in my hands.

There is one point more upon which I would like to say a few words. Under the Medical Acts as they now stand Dr. Rentoul's resignation would entail upon the profession a series of double elections. The costliness and inconvenience of this arrangement are obvious. To restore as far as lies in my power the normal condition of affairs I shall resign my office when the term of the Representatives elected in 1896 expires—i.e., after I shall have served for four years instead of for the full period of five years for which you have elected me. Again thanking you,

I am, yours faithfully,

VICTOR HORSLEY.

To the Registered Medical Practitioners of England and Wales.

LADIES AND GENTLEMEN,—I beg to return my most heartfelt thanks to the 6112 registered medical practitioners who, with only a few days' notice of my candidature, voted for me in the recent election. When I consider that many of my friends were unable to assist me on account of pledges given before my candidature was announced, I feel very grateful for this remarkable expression of confidence on the part of so large a number of my profession.

I am, your obedient servant,

Birmingham, Oct. 18th, 1897. B. WALTER FOSTER.

To the General Practitioners of England and Wales.

LADIES AND GENTLEMEN,—It is with a full—indeed, a keen—appreciation of the firm adherence to my cause of many of my professional friends that I address myself to you with earnest thanks at the close of this election, wherein I appear in the last place. For it must have been apparent to you who voted for me, so soon as the two rivals—Mr. Victor Horsley and Sir Walter Foster—came upon the field with their powerful organisations and the glamour of their names, that they would attract nearly all the interest of the election, and would swiftly draw such a following that the rush would detach a large number of adherents from the other candidates, and sweep their voting papers into the scumper with the rest. That this was so was exemplified upon a large scale by what happened in the grouping about Mr. Jackson. There the mass was disintegrated with the assent of its central figure, who hailed his constituents to gather with him in the wake of the particular rival he selected.

But the polling being over, what is its practical outcome? A man of capacity has been chosen, but from whence? From the ranks of the consulting men of London; and thus our distinctive representation, the increase of which we are earnestly demanding, has been reduced from five to four. That Mr. Horsley has much information of the needs of the medical practitioner is notorious, and that he will work honestly goes without saying. But mark! It is information alone which he possesses, not experience. In his London meeting he admitted that no one in the Council had done more for the profession than Dr. James Glover, and we all know that Dr. Jas. Glover is a general practitioner of long standing and experience; and Mr. Horsley had before said in his brief, that there were two gentlemen of our body, friends of his own, who are worthy of the office he himself was seeking, and if either of these would stand, he would not. Otherwise, he would compete in the interests of us all. Ingenuousness does truly mark our earlier days!

Well, the electorate have taken Mr. Horsley at his own estimate and have opened wide the portals for his entry, whilst thoughtful men have looked on with wonder and concern. But when the dust of contest shall have settled upon the field, and the sunlight and fresh air of truth and common sense shall make our vision and our retrospect clear, we shall perceive that the profession has uttered to itself a stern rebuke and has, in the darkness, made a lash for application to its own body, and at the same time has given to the ill-natured critic of our profession a chance to smile and say, "It serves you right."

Adieu for this time, and with thanks once more heartily felt and respectfully tendered,

I am, your faithful servant,

Devonshire-street, Portland-place, Oct. 20th, 1897. E. DIVER.

THE ASSOCIATION OF CORPORATE AND MEDICAL REFORM AND THE DIRECT REPRESENTATIVES.

WE have received the following letters with a request for their publication:—

11, Adam-street, Strand, W.C., Oct. 16th, 1897.

SIR,—We are requested to represent that its next meeting being on Tuesday, Oct. 19th, our committee will feel obliged by the favour of a reply to the letter addressed to you covering a series of questions submitted to candidates at the recent election to a vacancy in the General Medical Council. Until the movement for medical reform is taken up by his own constituency it is, we feel sure, unnecessary to explain that there can be no suggestion of a claim to a reply from the Direct Representative for Scotland, and his opinion is invited solely because, as has before happened in the

Digitized by Google

history of both countries, lovers of freedom and justice in our country may well hope to receive both sympathy and help from his; and we feel every confidence that a request arising from a spirit of courtesy and deference will be met in the same spirit.

Our committee can have no doubt of the will of all the Direct Representatives to act in harmony with the aspirations of their constituencies, yet in the adoption of a course of policy intended to extend to an appeal to Parliament and the nation, an expression of their views in order to enable all appearance of disunion to be avoided would afford valued assistance in deciding upon the most proper measures.

We have, &c,

(Signed) W. G. DICKINSON,
R. B. ANDERSON,

Hon. Secretaries of the Corporate and Medical Reform Committee.

To Dr. J. Grey Glover and Dr. William Bruce.

25, Highbury-place, N., Oct. 18th, 1897.

DEAR MR. SMITH,—I hope you will forgive me for not sooner replying to a letter from a body calling itself the Executive Committee of Corporate and Medical Reform, of which you are the chairman, in which letter are enclosed some thirty or forty questions with a request that I should give a reply to each of them.

I hope you will not think me guilty of any personal discourtesy if I ask you to excuse me complying with this request. Such elaborate heckling is bad enough during an election, and from gentlemen in whom one recognises some authority to speak for the profession or for a considerable section of it. The present is not such an occasion. In spite of the opposition of most of the gentlemen whose names I see in your circular, I am by the favour of the profession—not your delegate as you seem to think—but its representative now for the third time. I claim to be treated with some trust and not cross-examined like an uncertain witness by gentlemen who have constituted themselves, very superfluously as I think, into a new association. I do not think it in the interest of the profession that any half-dozen gentlemen can meet in any small room and dub themselves a new association. Surely we have enough associations already. In a paragraph in the *Times* of Oct. 12th, having clear internal evidence of being supplied by your executive committee (in course of formation), mention is made of the Association of Fellows of the College (Royal College of Surgeons of England?), the Society of Members of the College, the Incorporated Medical Practitioners' Association, the London and Counties Medical Protection Society, the Medical Defence Union, and various other societies and the British Medical Association.

What can be the excuse for another medical association and what its function? The answer is to be gathered from the same paragraph. It is to push them all on and energise them—to be a sort of goad or *vis a tergo*. The modesty of this function, self-assumed by a few gentlemen who are by no means silent members of the other associations, strikes me, as does their happy belief that this last grand new association is necessary to move the greater associations into use and activity. These associations are doing their best. Two or three of them would do all the profession needs if they were loyally supported and not distracted by little competitive bodies whose vanity seems to be in the inverse ratio of their age and numbers. I must, therefore, respectfully decline to recognise the need of your association or its right to question men elected and trusted by the profession of England and Wales as members of the Medical Council.

But my chief reason for declining to answer your numerous questions, which remind me of a celebrated long programme which brought its authors to grief, has yet to be stated. It is not that I do not sympathise much with some of your chief objects, but that I lack confidence in your judgment, in your impartiality, and that I disapprove of the methods by which you propose to realise your objects. You propose to memorialise the Medical Council—a perfectly legitimate procedure. But you intimate in the *Times* an intention, in the event of your appeal to the Medical Council being unsuccessful, of petitioning Parliament and being heard at the Bar of both Houses. I seem to detect in this proposal a development of a threat made by one of my colleagues in a celebrated speech of "shaking the Medical Council to its centre," and, this failing, of "going to Parliament." Whether your committee could claim the privilege of appearing at the Bar is perhaps open to question. But the proposal seems to me dramatic and ridiculous. Were I to join you in attempting to carry it out we should not only make ourselves appear ridiculous—which might be a small matter—but we might bring Direct Representation itself, and even the great profession of which we are all proud to be members, into discredit. It is not thus that the many grievances of medical practitioners are to be redressed or the constitution of the Medical Council is to be improved. I must therefore ask to be severely and entirely disassociated from the authors of such a proposal.

I am, Sir, your obedient servant,

JAMES GREY GLOVER.

To Joseph Smith, Esq., M.R.C.S. Eng., &c., Chairman of the Corporate and Medical Reform Committee.

[COPY.]

The Castle, Dingwall, N.B., Oct. 17th, 1897.

DEAR SIRS,—I have to thank your committee for the compliment they have paid me in addressing me on the subject of their memorial and in doing me the honour to ask me to to sign it. I trust they will not suppose for one moment that I do not sympathise with the feelings which prompted them to issue and to ask for support for their memorial, when, after full consideration, I refuse to adhibit my name to the document. If the committee carry out their intention of presenting it to the next meeting of the General Medical Council I shall frankly and freely express my views, which I hope will be such (as far as they go) as to merit the committee's approval. It humbly seems to me an expression of opinion at this time would be both premature and, let me add, in my personal and unadvised judgment, somewhat discourteous to my colleagues of the General Medical Council. Please excuse haste, as I must write now to catch the post so as this may reach you on Tuesday, and believe me to be,

Yours truly,

(Signed) WILLIAM BRUCE.

To Messrs. Dickinson and Anderson, London, Hon. Secretaries of the Corporate and Medical Reform Committee.

THE EXTENSIONS AT THE BATHS OF BATH.

IT is needless in a medical journal to say anything about the virtues of the Bath waters, but it is perhaps necessary to remark that these virtues are not appreciated by the public as they should be. The corporation of that city in whose hands the control and care of the baths are vested have of late years pursued the wise policy of improving the accommodation and the appliances in every possible way, and the latest addition, a magnificent concert-room and promenade around the old Roman bath, was opened to the public on Oct. 18th by H.R.H the Duke of Cambridge. The day chosen, St. Luke's Day, doubtless on account of the association of that saint with the medical profession, was unfortunate in one way in that it clashed with the Harveian Oration and the meeting of the Royal College of Physicians of London, by which many metropolitan medical men were prevented from accepting the hospitality so kindly offered by the corporation and the medical men of Bath. The proceedings were eminently successful in every way. To begin with the weather was perfect and the beautiful city was looking its best. His Royal Highness on arriving first received the Freedom of the City and afterwards laid the foundation-stone of the new Art Gallery. On the conclusion of this ceremony he was conducted to the building forming the additions to the Pump Room. The promenade or concert-room is a well-proportioned chamber, some 80 ft. long by 40 ft. wide, mainly in the classical style, with Renaissance decoration. At right angles to this runs the old Roman bath which has been lately uncovered; the water is open to the sky at present, though formerly it was roofed in, and the walls and pillars supporting this roof are still to be seen running round the central bath for about the height of four or five feet. Under the present scheme the bath has been treated as the impluvium in the atrium of an ancient Roman house. The external walls are carried up from the ancient walls to form the court, and plain Doric pillars support the flat roofs over the ambulatories at the sides and ends. On the east, south, and west sides are statues of eight of the Roman generals and emperors who had to do with the conquest and occupation of Britain. These are the work of Mr. G. A. Lawson, whilst the architect of the surroundings of the bath is Mr. J. M. Brydon, who

Digitized by Google

also designed the concert-room. The Duke of Cambridge having taken his seat, Mr. R. H. Moore, the chairman of the Baths Committee, gave a short but most interesting account of the baths and the various improvements and means for utilising the waters which have been carried out from time to time. That these additions were worth carrying out from a purely commercial point of view was shown by the fact that since they had been in use the income to the city from the baths had increased from £2000 per annum to over £6000. Though the Corporation of Bath naturally rejoiced over this it was not simple selfishness, for the increased and increasing use of the baths meant relief from pain and suffering for many hundreds of invalids. His Royal Highness then, after a short speech of congratulation, declared the additional buildings open. After this the mayor, Mr. C. Woodiwiss, entertained some 250 guests to luncheon in the Guildhall. Among the medical men present were Dr. Allchin, Mr. Lennox Browne, Dr. Cholmeley, Dr. Coupland, Dr. Curnow, Dr. John Harley, Mr. Reginald Harrison, Dr. Hensley, Mr. Cripps Lawrence, Mr. Macnamara, Dr. B. H. Rogers, Mr. Quarry Silcock, and Dr. James Taylor. Mr. Victor Horsley, who had been invited, was unfortunately prevented from being present.

After luncheon the medical visitors were given a private demonstration of the various methods of bathing employed and the different kinds of baths in use. All these were described and explained by Mr. Henry Freeman, F.R.C.S. Irel. A reception and tea were also held at the Royal United Hospital. In the evening the medical profession of Bath and the neighbourhood entertained their professional brethren at dinner. Altogether some forty sat down, Dr. L. A. Weatherley being in the chair. The dinner went off very well and reflected great credit on the indefatigable secretary of the Medical Reception Committee, Mr. W. M. Beaumont. The chairman proposed the health of the guests, which was responded to by Dr. John Harley.

After dinner the company proceeded to the reception given by his Worship the Mayor in the new concert-room. The old Roman bath was illuminated in good taste, the lamps being small and subdued and therefore not productive of any jarring effects, and the whole scene was one of great beauty. Bath, we think, may well be proud of the way in which the various entertainments were carried out, and her guests have every reason to be grateful. Mr. T. Sturge Cotterell, on behalf of the corporation, has spared no pains to impress upon the world at large the beauties and benefits which the city of crescents offers to all alike, while as more particularly concerning ourselves the Medical Reception Committee, through Mr. W. M. Beaumont and Dr. Bannatyne, were untiring in their efforts to show everything that could be seen and to extend an almost overwhelming hospitality. The corporation has intimated its intention of carrying out still further improvements, so that we do not feel ungrateful in suggesting one. Bath is pre-eminently the city in Great Britain which needs, and could support, a casino—we mean a place where the resident or visitor could just stroll in on paying sixpence or so and enjoy a cup of coffee, and listen to a good string band. Perhaps the new concert-room will be sometimes utilised in this way, but we fancy it would be better to have an additional building. It need not be more than a kind of large conservatory, but it must be properly managed, and the fault avoided which spoils so many places in London of ordering people about. This sin is especially in evidence at that notable failure from an entertainment point of view, the Imperial Institute, where the visitor is told he may not do this or that and may not go here or there, and when at length, after many trials, he does arrive at the "gardens," what does he find? An asphalte paved court, surrounded by brick walls, looking more like a prison exercising ground than anything else. We have sore need in this country of more opportunities of simple and cheap relaxation, and Bath is one of the places to show how they can be brought about.

THE SICKNESS AND PLAGUE IN INDIA.

THERE is an unusual amount of sickness and mortality in certain parts in India at the present time, and notably in the city of Bombay and in several of the towns and rural districts of that Presidency. According to the latest papers the mortality in Bombay at the present time stands at the very high rate of 52·83 per 1000. The epidemic of plague has not by any means ceased; on the contrary, it still prevails to some extent in Bombay, and even more so at Poona and Kirkee, and it seems to be slowly but surely creeping along rural districts and villages. According to telegraphic intelligence through Reuter's agency, of the 19th inst. an outbreak of what is believed to be plague has occurred in a village in the Jullundur district of the Punjab. Twenty-three deaths have been reported, and it is believed that the infection has been conveyed to the village from Hurdwar, which is situated on the Ganges, in the Saharunpur district. The situation altogether is not so satisfactory as could be desired and probably gives rise to some anxious consideration on the part of the authorities in India and this country. The prevalence of the disease, too, tends to increase during the winter. An elaborate scheme has been formulated for the sanitary improvement of Bombay which will cost a good deal to carry out, but no reasonable amount of outlay will prove so costly as the continuance of plague and other epidemic diseases.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6345 births and 3566 deaths were registered during the week ending Oct. 16th. The annual rate of mortality in these towns, which had declined in the nine preceding weeks from 29·5 to 16·2 per 1000, rose again last week to 16·9. In London the rate was 16·1 per 1000, while it averaged 17·5 in the thirty-two provincial towns. The lowest rates in these towns were 9·2 in Cardiff, 9·9 in Swansea, 10·9 in Halifax, and 11·6 in Croydon; the highest rates were 21·5 in Bolton, 22·4 in Liverpool, 23·6 in Preston, and 23·7 in Birmingham. The 3566 deaths included 415 which were referred to the principal zymotic diseases, against 514 and 434 in the two preceding weeks; of these, 127 resulted from diarrhœa, 89 from measles, 73 from diphtheria, 51 from "fever" (principally enteric), 39 from whooping-cough, and 36 from scarlet fever. No death from any of these diseases was recorded last week in Brighton; in the other towns they caused the lowest zymotic death-rates in Bradford, Croydon, Swansea, and Oldham; and the highest rates in Birmingham, Sheffield, Burnley, and Preston. The greatest mortality from measles occurred in Birmingham, Manchester, and Burnley; from whooping-cough in Derby; from "fever" in Gateshead; and from diarrhœa in Salford, Blackburn, Preston, and Sunderland. The mortality from scarlet fever showed no marked excess in any of the large towns. The 73 deaths from diphtheria included 45 in London, 4 in Liverpool, 3 in Plymouth, and 3 in Leicester. No fatal case of small-pox was registered last week either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 3725, against 3697, 3677, and 3692 on the three preceding Saturdays; 440 new cases were admitted during the week, against 358, 349, and 400 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 167 and 176 in the two preceding weeks, further rose last week to 268, and were 15 above the corrected average. The causes of 40, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Leeds, Hull, Newcastle-upon-Tyne, and in eighteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Nottingham, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 17·8 to 19·8 per 1000, declined again to 19·1 during the week ending Oct. 16th, but exceeded by 2·2 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from

Digitized by Google

12·8 in Aberdeen and 13·3 in Paisley to 21·7 in Edinburgh and 23·7 in Greenock. The 568 deaths in these towns included 29 which were referred to diarrhœa, 20 to whooping-cough, 17 to scarlet fever, 6 to measles, 6 to diphtheria, and 6 to "fever." In all, 84 deaths resulted from these principal zymotic diseases, against 78 and 73 in the two preceding weeks. These 84 deaths were equal to an annual rate of 2·8 per 1000, which was 0·8 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had declined from 20 to 12 in the three preceding weeks, rose again to 20 last week, of which 13 occurred in Glasgow and 3 in Leith. The deaths referred to scarlet fever, which had been 5 and 13 in the two preceding weeks, further rose to 17 last week, of which 7 were registered in Edinburgh, 4 in Glasgow, and 4 in Paisley. The 6 fatal cases of diphtheria also showed a further increase upon the numbers recorded in recent weeks, and included 3 in Glasgow and 2 in Edinburgh. The deaths referred to different forms of "fever," which had been 7 and 12 in the two preceding weeks, declined to 6 last week, of which 3 occurred in Edinburgh and 2 in Paisley. Of the 6 fatal cases of measles 5 were recorded in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 137 and 162 in the two preceding weeks, declined last week to 122, but exceeded by 35 the number in the corresponding period of last year. The causes of 34, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 28·3 to 21·9 per 1000, rose again to 24·0 during the week ending Oct. 16th. During the thirteen weeks of last quarter the rate of mortality in the city averaged 24·0 per 1000, the rate during the same period being 19·4 in London and 18·4 in Edinburgh. The 161 deaths registered in Dublin during the week under notice showed an increase of 14 upon the number in the preceding week, and included 14 which were referred to the principal zymotic diseases, against 20 and 17 in the two preceding weeks; of these, 7 resulted from "fever," 3 from diarrhœa, 2 from diphtheria, 1 from scarlet fever, and 1 from whooping-cough. These 14 deaths were equal to an annual rate of 2·1 per 1000, the zymotic death-rate during the same period being 2·0 in London and 2·8 in Edinburgh. The deaths referred to different forms of "fever," which had declined from 9 to 4 in the three preceding weeks, rose again to 7 last week. The 3 fatal cases of diarrhœa showed a marked decline from the numbers recorded in recent weeks. The mortality from scarlet fever also showed a decline, while that from diphtheria and from whooping-cough showed an increase. The 161 deaths in Dublin last week included 27 of infants under one year of age and 36 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a further decline from those recorded in recent weeks. Six inquest cases and 6 deaths from violence were registered; and 56, or more than a third, of the deaths occurred in public institutions.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR CROFTS is appointed for service in West Africa. Surgeon-Major Reade and Surgeon-Lieutenant Bowen have joined at Woolwich for duty. Surgeon-Lieutenant Brodribb is posted to the Station Hospital, Western Heights, Dover. Surgeon-Captain Wright has embarked for Malta. Surgeon-Lieutenant W. A. Ward embarked on the 22nd inst. at Tilbury in s.s. *Arcadia* for Bombay.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of the under-mentioned officers are replaced at the disposal of the Military Department:—Surgeon-Lieutenant Hooton (Bombay) and Surgeon-Lieutenant Standage (Bombay). Brigade-Surgeon-Lieutenant-Colonel Blood, A.M.S., to officiate on the Administrative Medical Staff of the Army, with the temporary rank of Surgeon-Colonel, vice Surgeon-Colonel E. Townsend, A.M.S., appointed Principal Medical Officer, Mohmand Field Force.

The under-mentioned medical officers of the A.M.S. have been detailed for duty with the 24th British Field Hospital, in place of Surgeon-Major Yourdi and Surgeon-Major Berryman, whose tour of service has expired: Surgeon-Major Woodhouse and Surgeon-Major Henderson.

VOLUNTEER CORPS.

Rifle: 12th Middlesex (Civil Service): Surgeon-Lieutenant E. M. Callender to be Surgeon-Captain.

THE WEIGHT OF CANDIDATES FOR COMMISSIONS IN THE ARMY.

Attention has been called to the orders regulating the height and weight of candidates for admission to Sandhurst and Woolwich and for army commissions. In the enlistment of recruits for the army, where the age of the recruit often cannot be accurately known, it was naturally found desirable that some rules and scales, deduced from a large and extended series of examinations and observations, should be laid down for general and medical guidance regarding height, weight, and chest measurement in relation to age. A large amount of statistical and other data exists, and the late Sir William Aitken embodied the results of these in his work on the growth of the recruit and young soldier. The outcome of all this analytical labour was to determine, approximately at any rate, what is or should be, the condition of the human frame in these respects at certain ages of life, and which was expressed by the term "physical equivalents." There cannot be any doubt that men of good build and of good physical strength and health are required for army life. But it is a matter of common observation that men of light weight are frequently very enduring, active, and energetic, both physically and mentally, and will, in the parlance of the day, "walk round" the heavier and altogether bigger samples of humanity in many field sports and exercises. Still, these favourable samples of light weights cannot, after all, be said to be the rule, and it is next to impossible to fix on a working formula or average that will satisfy all. It is contended that the scale of weight laid down and required for young officers for the army is too high, and that it would have excluded some of our most distinguished officers; that many athletes are the reverse of fat and that light weights frequently possess superior powers of endurance—"staying power," as it is called; and there is no doubt a good deal of truth in these statements. It is well known that, owing probably to differences in diet, hygienic care, and outdoor games, the youth of the well-favoured non-labouring classes compare favourably with the artisan or labouring class of the English population in size, weight, and stature. It is often difficult to determine from the physical examination of a youth what he will become later in life. We suspect that many boys of sixteen years of age, 5 ft. 4 in. in height, do not weigh 8 st. 8 lb., although at twenty-one or twenty-two years of age they may develop into fine, active young men in every way well fitted for military officers. But the age of sixteen years does not count in the case of candidates for Sandhurst and Woolwich, for they are rarely so young and commonly of about eighteen years of age when they go up for the examination. If the figures in the regulations be compared with the averages in anthropometrical tables they will, we think, be found to have been fairly fixed. On the other hand, it is an exaggeration to represent that the regulations as to weight in correlation with height and chest measurement required by the army authorities mean fat young men. The young officers of our army, as seen at any military club, strike us as a fine body of well-grown young fellows and they are certainly not fat. What seems to us a legitimate source of complaint is the existence of any rigid rule at all about matters which should be mainly left to the judgment of the examining medical officers. Scales and formulæ should be used as guiding indications rather than as absolute rules for invariable application.

IMMEDIATE LAPAROTOMY IN WOUNDS OF THE ABDOMEN.

A paper on this subject by a French military surgeon named Caillet was read by M. Chauvel at a recent meeting of the Académie de Médecine, the author having based his remarks mainly on two cases which were related in detail. In the first a non-commissioned officer received a revolver shot point blank in the lower part of his abdomen, and an hour later was taken to hospital. The officer on duty dressed

Digitized by Google

the wound with iodoform and applied a bladder containing ice. The following morning when Dr. Caillet saw the patient, six hours after the injury was inflicted, he was in a good condition, the temperature was 96·8° F. and the pulse was 80; there was no vomiting, hiccough, or dyspnœa. By four o'clock in the afternoon, however, unfavourable symptoms had set in, and at 7.30 operative interference was decided on. Median laparotomy disclosed four perforations of the small intestines, and the cavity of the peritoneum contained some doubtful-looking fluid, with particles of food and false membrane. Recovery, which was delayed by an attack of pneumonia, took place in about six weeks, the missile coming away in a stool on the ninth day. In the second case a dragoon was stabbed in the left iliac region and immediately vomited some coffee he had just taken. Four hours later he was admitted to the Vincennes Hospital, his general condition being then satisfactory. There was no nausea and his pulse beat firmly at 70. An attempt was made to probe the wound, but the stylet could not be introduced. As perforation seemed uncertain an expectant treatment was adopted, and the next morning the patient was so well that he was allowed several spoonfuls of milk. A few hours after this a complete change took place and urgent signs of generalised peritonitis showed themselves. Median laparotomy was at once performed, but the patient was so weak that only the small intestine could be examined, the result being negative. The abdomen was then closed, after the cavity had been washed out with warm artificial serum. Shortly afterwards the man died, and at the post-mortem examination it was found that the large intestine had been pierced. The author believes that if preventive laparotomy had been essayed both patients would have been saved. There is no intrinsic danger in laparotomy nowadays, he says. Then why delay it even in the most doubtful cases? In the instances cited the impossibility of sounding the wounds contributed largely to the postponement of the operation; but considering the small-sized projectiles now in vogue this method of establishing a diagnosis should not be accorded too much weight, especially when anæsthesia has not been employed. Exploration is, no doubt, of great value where practicable, but inability to effect it is no proof of the absence of perforation. Statistics may be unfavourable to immediate laparotomy in penetrating wounds of the abdomen, but the author, nevertheless, maintains that it is generally indicated, and in this opinion he apparently has the support of M. Chauvel.

CHOLERA IN INDIA.

The news from the headquarter half of the 1st Battalion of the Shropshire Regiment stationed at Sitapur, not far from Lucknow, North-west India, shows that a severe outbreak of cholera has occurred. It is reported that forty non-commissioned officers and men have died from cholera. It is too early to learn any details, but assuming the outbreak to have been a very sudden one it looks like water poisoning; but if that be so, how did it occur on such a scale? Sitapur is, generally speaking, a healthy station, and how did the *comma bacillus* gain an introduction into the affected community?

THE SICKNESS AMONG THE TROOPS IN THE TOCHI VALLEY.

We are glad to hear from the last file of Anglo-Indian papers up to the 2nd inst. that the health of the Rifle Brigade is somewhat improving. They had lost up to date one officer and forty-four men. The valley at this time of year is unhealthy, and a good deal of sickness, mainly of malarious origin, prevails. The temperature during the day has been great—99° F. at Saidgi in a double fly tent; but it will soon, or already has, become cooler.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The autumn meeting of the South Western Division of this association will be held at Brislington House, near Bristol, on Oct. 26th at 2.45 P.M. Dr. Goodall will communicate a paper on the Systematic Collection of Anthropometrical Data in Asylums; Dr. Morton will read notes of a case and open a discussion on the Making of Wills by Certified Patients, and the Duties of Medical Men in Regard to This; Dr. Blachford will read notes on the Order of Disappearance of Rigor Mortis from the Body as observed at Autopsies on the Insane; and Dr. Briscoe will report a case of Fracture of the Fibula in a Melancholic, with Remarks on Fracture in Insane People.

Correspondence.

"Audi alteram partem."

THE JENNER SOCIETY AND VACCINATION.

To the Editors of THE LANCET.

SIRS,—It is thought desirable to put on record in an unquestionable form the opinion of medical officers of health as to the relative merits of vaccination and "sanitation" as preventives of small-pox. Such an expression of opinion will, it is conceived, be the most effective answer to the views to which the statement of the two dissentient members of the late Royal Commission on Vaccination has given so much currency, that "sanitation" can be safely relied on, not as an adjunct to, but in the place of, vaccination, notwithstanding the opinion of the rest of their colleagues to the contrary.

The following declaration, whilst affirming the report of the late Royal Commission, that "sanitation cannot be relied on as a substitute for vaccination, also confirms two other conclusions contained in the report—that vaccination, especially by the use of calf lymph, is free from any serious danger, and that to perpetuate the protection against small-pox afforded by vaccination in infancy it is expedient to repeat the operation at a later age. It has already been signed by upwards of 850 medical officers of health in Great Britain, India, and the colonies. The signatures of those who have no pecuniary interest of any kind in vaccination, nearly 250 of the above number, include those of officers to a number of English, Welsh, and Scotch counties, the metropolitan and many combined provincial districts, and nearly all the large cities and towns. It is still in process of signature, and will, it is believed, be endorsed by medical officers of health in all parts of the world.

I am, Sirs, yours faithfully,

FRANCIS T. BOND, M.D.,
Honorary Secretary of the Jenner Society.

Gloucester, Oct. 7th, 1897.

Declaration.

We, the undersigned, actually or recently medical officers of health, think it right, in view of assertions which have been published, with some appearance of authority, as to the efficacy of "sanitation" as a substitute for vaccination in dealing with small-pox, to make the following statement:—

1. As responsible sanitary officials, to whom the care of the health and lives of the community is especially entrusted, we have every inducement to give due weight to the value of "sanitation" in the widest sense of the term for the prevention of small-pox as of other forms of infectious disease. We include in that term good drainage, the removal of refuse, the supply of pure air and water, and all other conditions which are calculated to fortify the body against disease in general.

2. We are no less alive to the importance of those special precautionary measures which experience has shown to be so valuable, when effectively used, to arrest the spread of infectious disease, such as the immediate notification of illness, the efficient isolation of the sick and of those who have been exposed to infection, and thorough disinfection of persons and things.

3. While thus fully appreciating the value of these agencies for such purposes we unhesitatingly declare our belief that they cannot alone be relied on either to prevent or to stamp out epidemics of small-pox.

4. We believe that the only trustworthy protection at present known against small-pox, alike for the individual and the community, is efficient vaccination in infancy and subsequent re-vaccination, and that the only effective way of stamping out epidemics of this disease lies in the free use of these agencies.

5. We are so thoroughly convinced that the dangers alleged against vaccination are, as the Royal Commissioners have asserted, "insignificant," even without the additional safeguards which the Commissioners have recommended, that, in common with nearly the whole of the medical profession, we not only prescribe it generally, but use it for ourselves, our families, and others, in whose welfare we are personally interested.

6. We repudiate the calumny which has been freely circulated that either we or other members of the medical profession have been influenced in forming or expressing our belief in vaccination by any consideration other than that of the public health, but we think it well to add that a considerable number of us derive no emoluments of any kind from the practice of vaccination.

THE LANE MEDICAL LECTURES.

To the Editors of THE LANCET.

SIRS,—Mr. Christopher Heath, late President of the Royal College of Surgeons of England, delivered during the month of September the second course of the Lane Medical Lectures recently founded in connexion with the Cooper Medica

Digitized by Google

College in San Francisco. This course was addressed especially to the students of that school but was also attended by some hundreds of medical men of the Pacific coast; the attention of the audience to the teachings of this eminent English surgeon was markedly intense and reverent. The closing lecture, "A Century of Surgery," was replete with illustrations of the advancement of surgery during the nineteenth century. As a contributor to this progress great distinction was given to Lord Lister. Other men, both Europeans and Americans, who have aided in this advancement received appropriate mention. The lectures of Mr. Heath were characterised by a judicious blending of the science and the art of surgery; of the one not so much as to be tedious, of the other enough for guidance to the surgical practitioner. He taught how in boldness not to be rash, how in conservatism not to be inactive. For the appreciated and satisfactory work done by Mr. Heath in San Francisco the New World now brings its honest tribute to add to the honours and renown, so well and worthily won, with which the Old World has so long distinguished him.

I am, Sirs, yours faithfully,

LEVI COOPER LANE, M.D., M.R.C.S. Eng.,
President of Cooper Medical College.

San Francisco, Sept. 29th, 1897.

"INFECTIVE SWINE DISEASES": A CORRECTION.

To the Editors of THE LANCET.

SIRS,—I find in your issue of Sept. 25th the report of my remarks at the Montreal meeting of the British Medical Association on the infectious swine diseases in the United States, in which this statement occurs, "the term 'Schweineseuche' seems to relate to what he understood as 'hog cholera.'" This is a very unfortunate typographical error. I stated that the German "Schweineseuche" and the American swine plague appear to be identical.

I am, Sirs, yours faithfully,

Ithaca, N.Y., U.S.A., Oct. 15th, 1897. V. A. MOORE.

"THE PREHENSILE POWER OF THE HANDS OF THE HUMAN INFANT."

To the Editors of THE LANCET.

SIRS,—Dr. Walter Kidd's argument is a little difficult to follow. Apparently he maintains that the prehensile power of the hands of new-born infants is merely reflex, and that, therefore, it does not afford evidence of man's descent from a lower animal (e.g., ape). I fancy no one will deny that the action is reflex, for it hardly comes within the category of instinctive action, and it certainly is not rational. But all reflexes have meanings, and, since this particular reflex is useless to the human infant but would have been highly useful to a simian ancestor, surely it is not unreasonable to suppose that it is a "vestige"—just such a vestige as the embryonic branchial arches. Dr. Kidd himself mentions a fact which may be used in support of Dr. Robinson's theory; he says the reflex disappears in a few weeks. This is true, but it is also true that reflexes and instincts which predominate in the lower animals (e g, fish) are to a great extent lapsed and replaced by rational action in the higher (e g., men).[1] According to the doctrine of evolution, the individual in his development recapitulates the life-history of his race, for which reason the infant at birth is much more simian in type—e.g., as regards his features and his in-turned feet—than he is later, whence it follows that we may expect some reflexes, useful to the ape but useless to the man, to be present at birth, but to disappear later. It further follows that since the foot diverged from the quadrumanous type at a much earlier date than the hand its reflex prehensile power is on that account still less. Dr. Robinson's theory does not, indeed, supply proof that man has descended from an ape-like animal, but it affords strong corroborative evidence. The proofs are very massive and for that very reason cannot be entered upon here, but a striking passage from Professor Weismann may be quoted: "It is not only that, in the light of this theory, numerous facts receive for the first time a meaning and a significance; it is not that, under its influence, all the ascertained facts can be harmoniously grouped together; but in some departments it has already yielded the highest results which can be expected from any theory—it has rendered possible the prediction of facts, not indeed with the absolute certainty of calculation, but with a high degree of probability. It has been predicted that man, who in the adult state only possesses twelve pairs of ribs, would be found to have thirteen or fourteen in his embryonic state It has been predicted that in this early period in his existence he would possess the insignificant remnant of a very small bone in his wrist, the so-called 'os centrale' which must have existed in the adult condition of his extremely remote ancestors. Both predictions have been fulfilled, just as the planet Neptune was discovered after its existence had been predicted from the disturbance induced in the orbit of Uranus."

I am, Sirs, yours faithfully,

Southsea, Oct. 16th, 1897. G. ARCHDALL REID.

"THE IMMEDIATE REDUCTION OF ANGULAR CURVATURE OF THE SPINE."

To the Editors of THE LANCET.

SIRS,—Mr. Jackson Clarke's letter in THE LANCET of Oct. 16th calls attention to a point that is in some danger of being overlooked in the excitement that may attend the first introduction into this country of Dr. Calot's method of correcting the deformity of Pott's disease. The immediate deformity in this disease is of course due to destruction of bone in the anterior portion of the spinal column, while the posterior portion as a rule is unaffected. This deformity can no doubt be corrected by Calot's method, and it may be hoped that the gap thus inevitably formed *may* in time be filled up by new bony growth. But those who have observed the after-history of such cases must admit that the deformity generally goes on growing with the growth of the patient. This is doubtless due to the fact more or less of the growth centres in the front part of the column having been destroyed. Thus the continued normal growth of the posterior part of the spine unaccompanied by a corresponding growth in front must force the column into a curve if consolidation has taken place. The more extensive the caries the greater will be this secondary increase of deformity. Mr. Jackson Clarke does well to deprecate the description of such operations as "successful" immediately after their performance; but I would go farther than he, and would venture to say that the result cannot be judged till, not months only, but years have elapsed—i.e., when the stage of growth is ended.—I am, Sirs, yours faithfully,

Seymour-street, W., Oct. 19th, 1897. E. MUIRHEAD LITTLE.

THE EPIDEMIC OF TYPHOID FEVER AT MAIDSTONE.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

THOUGH the Maidstone people are slow to move, still, they have at last taken action. A public meeting has been held, and after a noisy debate it was decided to form a Ratepayers' Association which will admit as members all direct and indirect ratepayers. It seems only natural to conclude that there has been serious blundering or neglect. A reaction is already manifest in the public feeling with regard to the water company. More than one inhabitant of the fever-stricken districts has observed to me that it was all very well blaming the water, but they wished the authorities would look after the drains. If some members of the District Council are shareholders or directors of the water company, other councillors are owners of house property. In the face of the great calamity which has befallen the town the sufferers are naturally anxious to fasten the responsibility upon some one, and they are beginning to fear that the persistence with which the whole trouble is attributed to the water-supply may result in the avoidance of a full inquiry into other and contributory causes. On the other hand, the temptation to ascribe the entire blame to the water-supply is very great, for it simplifies

Digitized by Google

the problem to a marvellous degree. For many years the water from the Farleigh springs has been drunk, and it has never been shown that any harm resulted. Why, then, should the authorities have been more on their guard this year than on previous occasions? But so soon as an alarm was raised prompt action was taken. On Sept. 18th the water was suspected, inquiries were immediately made on the spot, and the supply from the Tutsham springs was cut off on the 20th. Not satisfied with this the whole of the supply from the Farleigh district was abandoned on the 29th. Considering that this latter measure exposed the town to considerable danger if a fire broke out, and that there were fairly good reasons to believe that it was only the Tutsham springs which were contaminated, it was scarcely to be expected that the whole of the Farleigh supply should at once be given up. Yet this has now been done, and the probabilities are that no Farleigh water will again be utilised. As the plant connected with this supply is supposed to be worth from £30,000 to £40,000 it will be said that the Company, by abandoning so valuable a property, will have given practical proof of disinterested public spirit. It will then be shown that an ample supply can now be obtained from other sources which cannot be contaminated, and thus it will be urged that all danger is completely removed, the problem satisfactorily solved, and that the authorities have nothing more to do than to rest on their laurels and be thankful. In a little while even the water company will be forgiven and its shortcomings forgotten.

The report of the Local Government Board should defeat any such manœuvres, but this report will not be of much use unless it is published at an early date. The inhabitants of Maidstone are primarily interested in clearly defining the responsibilities for what has occurred. Theirs is no theoretical or imaginary grievance. More than a hundred lives have been lost in consequence of the neglect in the removal of preventable causes. Great bodily misery, physical suffering, and financial distress which might have been prevented have been endured by hundreds of families. Shall this calamity be glossed over and forgotten? Are the responsible authorities to be whitewashed by the mixing of some lime with the water-supply and the abandonment of the Farleigh springs? This would indeed be an easy way of getting out of the difficulty. But if the inhabitants of Maidstone could be so easily satisfied it must not be forgotten that though they are primarily interested the Maidstone epidemic is an event of world-wide importance. Other towns have to be told what has happened at Maidstone. They have their lesson to learn from this terrible example, and will they be satisfied when they are told that it is only necessary to turn off a stopcock here, to turn on another stopcock there, and forthwith one of the most complex scientific problems of the age is settled?

Such a solution can only be qualified as a shirking of the whole question. Unfortunately, the municipal elections are close at hand, and it is too soon to fix responsibilities between this and the beginning of next month, particularly as there has been no public inquiry to enlighten the electors. The Maidstone councillors urge with very great plausibility that this is not a suitable moment for an electoral contest. Party divisions and faction fights must be postponed in the face of the present distress. The authorities must present a united front to battle with the prevailing trouble. They must devote all their energies to coping with the epidemic and not lose precious time in canvassing the electorate; therefore, it is suggested that there shall be no contest, that no opposition shall be attempted, and that each councillor shall be re-elected. Certainly there are good grounds for saying that there should be no election contests in the midst of so serious an epidemic, but this is no reason why there should be no contest after the epidemic is over; on the contrary, it is absolutely indispensable that the inhabitants of Maidstone should have full and ample opportunity of examining the whole question and then of pronouncing their verdict by means of an election, otherwise our boasted self-government is reduced to a mere farce. If Maidstone authorities are to avoid censure by deciding, when difficulties arise, that there shall be no contested election, such a proceeding will establish a dangerous precedent by which elected bodies will escape the responsibilities that accrue from their blundering.

There is no objection to the Maidstone councillors remaining in office for a few weeks longer. This may be convenient under the present circumstances, but if it is justifiable to postpone the electoral contest for a few weeks it would be most unjustifiable to postpone it for several years. If, therefore, the present council succeed in preventing a contest, and consequently remain in office, they should first take a solemn and public pledge not to retain their position for more than a few weeks. It should be clearly understood that in, for instance, three months' time they will one and all resign, and thus force on another election which this time would be contested. Otherwise the council will lay itself open to the gravest accusations. This is a point on which the Maidstone Ratepayers' Association might with advantage insist before it is too late. It is not because there is so much evidence to show that the water has been the medium of spreading the disease that therefore there is nothing else to be done but to alter the water-supply. On the contrary, there is also much evidence to show that there were other contributive causes which must be discovered and removed. It should be borne in mind that there has been typhoid fever in Maidstone in former years which was in nowise put down to the water-supply, that there are now some cases of diphtheria which are not attributed to drinking water, and that the number of cases is increasing in spite of the improvement in the water-supply. This is so much the case that the wisdom of opening a *crèche* may be questioned. The *crèche* which is now about to be inaugurated will undoubtedly render great service to poor families where there are cases of typhoid fever, but by bringing many children together it may help to spread diphtheria. Thus, not only in regard to the typhoid fever epidemic, but in respect to the spread of diphtheria, a general inquiry into the sanitary condition of the town dealing not only with the water-supply, but also with the housing of the poor, private drainage, public sewers, the removal of refuse, &c., is imperatively needed. Great vigilance must be exercised so that this investigation is not at first postponed and then altogether abandoned.

To show that other issues are involved I might mention, for instance, how many persons have complained to me as to the difficulty they experience in obtaining the removal of the refuse from their dustbins. This is not done by the municipality, but by a contractor, and in several instances I found that the refuse had been allowed to remain for more than a month, and that the visits of the dustman were few and far between. Is it necessary that a sensational epidemic directly attributable to dustbins should occur before attention can be called to this obvious neglect of public duty? But, above all, the drainage of the whole town must be thoroughly examined. There is evidence enough to show that at least an inquiry is necessary. Taking, for instance, Buckland Hill, it will be found that the inhabitants there are much troubled by the question of sewer ventilation. A secondary main runs down this street and falls into the principal sewage collector at a very short distance beyond the point where it is joined by the syphon that has passed under the river and brought all the sewage from the eastern side of the town. At the lower part of this street there was a ventilator, but a year or so ago a case of typhoid fever occurred in the house nearest this ventilator. A little higher up there is a magnificent tree which has been allowed to remain in the very middle of the roadway. This tree was supposed to mark exactly the centre of the county of Kent, and for this reason and on account of its beauty it has not been felled; but after the case of typhoid fever which happened in the lower part of the street the tree was utilised as a support for a ventilating shaft, and the ventilator lower down was closed. No sooner had this been done than the inhabitants of the house that stood nearest and on the same level with the tree found that bad odours were blown from the ventilating shaft through the bedroom windows into the upper part of their house. This nuisance seemed so serious that the occupier of the villa in question wrote to the Local Government Board. Evidently he had greater faith in the central than in the local authorities. Some correspondence ensued, and finally a few more feet of piping were added to the ventilator. This, however, did not put an end to the odours. They no longer penetrated the upper windows of the villa nearest to the tree, but invaded the next villa, which stands on a higher level and therefore came into line with the increased height off the ventilating shaft. Now, it should be noted that in the house which has thus been freed from the odours given off by the shaft there has been no case of typhoid fever, but next door, where the odour now prevails, there is a case of

Digitized by Google

typhoid fever, yet both houses were equally supplied with the Farleigh water.

At the top of Buckland-hill the main sewer turns to the right up the London-road, and then a little further turns again, this time to the left up the Queen's-road. These are very sharp angles for a main sewer.[1] It is very probable that deposits are formed at these points. In any case, at both these corners are street ventilators that give off very foul odours, as I can testify from unpleasant personal experience. There have been several cases of typhoid fever between these two ventilators, though this is one of the best and wealthiest quarters of the town. In the house at the corner of the London-road and the Queen's-road, nearest to what was, at the time of my visit, the more obnoxious of the two ventilators, there is a very severe case of typhoid fever. Indeed, it may be observed in walking through the streets in the western part of the town that where tanyard refuse is put down to prevent the noise of vehicles disturbing the sufferers, and thus testifying to the existence of cases, a sewer ventilator will be found close at hand. This may be a coincidence, but in the several cases which I examined it was a fact. It is also notable that in speaking of the 19 cases of typhoid fever notified in the year 1896 the medical officer of health says in his annual report that "faults of drainage and sewer ventilation nuisance were the ostensible causes in some and direct contagion through nursing in others. Except that 3 cases occurred in Milton-street and 2 on Buckland-hill there was no particular coincidence as respects to locality." Now these two localities stand out very prominently in the present epidemic. Milton-street is one of the thoroughfares where there have been the greatest number of cases, and here the sewer occasions much trouble and has been dug up, repaired, and altered several times, while on Buckland-hill the sewer acts as a ventilator to the main collector that passes below at the foot of the hill. That these facts are not ample enough to prove a theory I readily admit, but they suffice to indicate the necessity for an inquiry. The point to ascertain is whether those houses and localities which suffered most were exposed to sanitary conditions which were not as good as, or which were worse than, those prevailing in other localities where there were not so many cases. Such an inquiry would probably lead to the carrying-out of other sanitary improvements besides the alteration of the water-supply.

In the meanwhile, and whatever neglect there may have been of sanitary questions in the past, it must be acknowledged that the local authorities have displayed great energy in dealing with the actual epidemic. The fitting-up of emergency hospitals has been no light task. Everything was wanting. The houses and the schoolrooms utilised had not the necessary sanitary conveniences. Closets and new drains had to be hastily put in, and it was impossible to find in a small town like Maidstone all that was required. On the other hand, to send up to London involved a loss of time. The work had to be continued day and night without a moment's respite. Nor was it easy to get together some 300 beds for the patients and to lodge more than 100 nurses. Then the patients and nurses had to be fed, and this involved the organisation of a commissariat department which was altogether out of the ordinary attributes of local administrative work. But soon another difficulty arose. A large amount of linen accumulated which was dangerously soiled by the patients. If this linen was scattered over the town and washed anyhow and by anybody the consequences were likely to be very serious. The medical officer of health, Mr. Matthew A. Adams, thereupon conceived the idea of establishing a public laundry for dealing exclusively with the infected linen. With the very efficient aid of Mr. Jackling, the sanitary inspector, a steam laundry, with all the most recent and improved machinery, was promptly opened. Carts are now sent round the town with numbered canvas bags. The linen from each patient is placed in a separate bag distinguished by its number. On reaching the laundry the bags without being opened are plunged in a large copper, where their contents are thoroughly disinfected by prolonged boiling. Then only are the bags opened and each article marked with a number corresponding with that of its bag, and can be washed in the ordinary manner. But so great is the amount of the work that had to be done that it was necessary to establish four large boilers set in solid brickwork, and to put up two huge tents seventy-five feet in length in which the linen is sorted. Another great difficulty soon arose. How was so large a quantity of linen to be dried? Fortunately, in a field opposite there were two oast houses for the drying of hops. These curious-looking, cone-shaped structures are familiar to all who travel in hop-growing countries. In the lower part there is a furnace where smokeless anthracite coal is burnt. Above the furnace and just under the cone-shaped roof there is not a floor, but horsehair matting resting on rafters. It is on this matting that the hops are placed to dry, as the heat passes through readily. For laundry purposes it was necessary to construct a framework all round the roof above this matting so as to hold ropes or poles on which the linen is hung to dry.

The borough surveyor on his side has had no easy task in looking after the flushing of the sewers and of the drains in the houses where there have been cases of fever. It has been necessary to procure and then fit a long hose to all the watering-carts. This hose is carried through the houses and the closets are thus flushed from the watering-carts that stand in the street. Sometimes a hundred gallons of water is thus discharged into a house drain or closet. Then another service of carts had to be organised to take round drinking water while the water-supply mains were being disinfected. The people have very fully responded to the instruction that they were to let their taps run so as to get the lime out of the mains and the branch pipes, for no less than 500,000 gallons of water were thus allowed to escape in about four hours. The smell of the lime is very persistent, and it is anticipated that there will be a tremendous waste of water before this has been completely washed out of the pipes. Under these circumstances the water-supply may run short for a little while; but when once the inhabitants are satisfied that there is no longer any trace of lime in the pipes the supply of water now secured will be ample, and this, of course, without using any of the condemned Farleigh water.

The distribution of the cases of typhoid fever still corresponds with that of the Farleigh water. The last calculation made brings us up to the date of Oct. 15th. At that time a total of 1654 cases had been notified, and about fifty cases have occurred since. Of this total 714 were inhabitants of the Western district and 94 were reported from the asylum, which is also in the west. In the north-east there were 554 cases and in the south east 204 cases. Thus in the three districts where the Farleigh water was drunk there were 1566 cases. The remaining 88 cases occurred in low-lying central districts where the water drunk comes from Cossington and Boarley. Perhaps all these 88 patients had drunk some of the Farleigh water when visiting friends in other parts of the town. In any case a considerable number of them have been proved to have done so. The wonder is that there have not been more victims in the centre of the town, as it is so near and so easy to step out of that district into the districts which used to be supplied with the Farleigh water. Now, however, that no more of this water is drunk the epidemic is evidently subsiding. The local authorities will therefore soon have time and leisure to study the predisposing causes and ascertain why some localities suffered more than others which had the same water-supply.

[1] See Map published in THE LANCET of Oct. 9th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University College, Liverpool.

THERE were twenty-five entries (including three ladies) for the new course of lectures on Sanitary Science, which number is considered very satisfactory. From eighteen to twenty students are attending Professor Boyce's pathological class at Ashton Hall. Ten gentlemen are also pursuing bacteriological investigations at the evening class, also under Professor Boyce's supervision.

Liverpool Medical Institution.

The first meeting of the session was held on Oct. 7th, when the President, Dr. Caton, delivered the inaugural address, the subject of which was Notes of a Visit to Poland and Russia on the occasion of the Twelfth International Medical Congress (with lantern illustrations). The meeting was exceptionally large, and much interest was evinced in

Digitized by Google

the views of the principal places of interest in Warsaw, Moscow, St. Petersburg, and Helsingfors. The members and associates were afterwards entertained by the President to supper *à la Russe*, followed by a smoking concert, which was enlivened by songs and recitations.

Liverpool Royal Infirmary.

The following house appointments have been made at the Royal Infirmary: House physicians: Dr. H. M. Crake, Dr. E. E. Laslett, and Dr. D. G. Hurter. House surgeons: Dr. J. E. Smith, Dr. F. S. Pitt-Taylor, and Dr. J. H. Willett. Resident medical officer to the Lock Wards: Dr. H. M. Henderson. Dr. Laslett won the Torr Gold Medal for Anatomy at University College, Liverpool, in 1894. Dr. Crake obtained the Gold Medal for Physiology in 1894. Both gentlemen held Holt Tutorial Scholarships for 1896–1897 at the same College.

Liverpool Medical Club.

The winter session 1897–98 for club debates and social entertainments commenced on Oct. 14th, when a successful smoking "social" was held. A goodly number of members were present and the evening passed off in a very agreeable manner.

Mr. Victor Horsley.

Mr. Victor Horsley's successful contest for the vacant seat on the General Medical Council was a source of much satisfaction to the medical profession in Liverpool generally, where his candidature was warmly supported. Mr. Horsley has been an honorary member of the Liverpool Medical Institution for some years.

Munificent Donation to the Liverpool Consumption Hospital.

Lady Willox, the wife of Sir John Willox, M.P., has given a donation of £2000 to the proposed new building fund of the Consumption Hospital. Her ladyship has always taken the warmest interest in the welfare of the hospital, where she is a constant visitor.

The New Mayor of Bootle.

Dr. John McMurray has been unanimously selected for the Mayoralty of Bootle for the ensuing year. Dr. McMurray, who is a comparatively young man, has been in practice in Bootle for about ten years, and is honorary surgeon to the Bootle Borough Hospital; he is also visiting medical officer to the Kirkdale Industrial Schools of the Liverpool Select Vestry. He was formerly assistant medical officer at the Liverpool Workhouse Hospital. Dr. McMurray is also a member of the Bootle School Board.

Birkenhead Medical Society.

The annual meeting of this society was held on Oct. 8th, Dr. Marsden, President, being in the chair. The following gentlemen were elected office-bearers for the ensuing year, 1897–98, viz.:—President: R. Sydney Marsden, M.B., D.Sc., F.R.S. Edin. Vice-President: Thos. S. Floyd, M.A., M.D. Dub. Treasurer: James Pinkerton, M.D., C.M. R.U.I. Secretary: Wm. Leask, M.B., C.M. Edin. Librarian: S. Wilkinson, M.R.C.S. Eng. Council: W. R. Floyd, B.A., M.B., Ch.B. Camb.; Joseph Blood, M.A., M.D., C.M. Dub.; J. H. Fardon, M.R.C.S. Eng.; Francis Johnston, M.B., C.M. Glasg.; and S. H. Nazeby Harrington, M.R.C.S. Eng.

Oct. 19th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Eye Infirmary, Newcastle-upon-Tyne.

A SPECIAL meeting of the above charity has just been held to take into consideration the financial position of the institution. The Mayor presided. The secretary made a statement to the effect that the expenditure had now for some years exceeded the income by some £300, and that capital had been spent to meet the deficiency. The Mayor alluded to the attempt recently made to amalgamate the Eye Infirmary with the Royal Infirmary, a proposition which the Royal Infirmary had rejected. Mr. M. Nesham drew attention to the small number of subscribers, and said at the present rate of expenditure the capital of the Eye Infirmary would be exhausted in four years. The Eye Infirmary is a very perfectly-equipped institution, admirably adapted for its purpose, and in years gone by was very successfully carried on. That it should have fallen upon such evil days is much to be regretted, and that means may be forthcoming to enable it to resume its old flourishing condition is much to be desired.

District Nursing.

Sunderland is one of the most enterprising towns in the north of England, and in the particular of district nursing it is not behind. A most influential meeting has just been held under the presidency of Archdeacon Long with the object of placing district nursing in Sunderland upon a firmer footing. The Marchioness of Londonderry, ever to the front in philanthropic movements in the north, delivered an excellent address on District Nursing. Mrs. Watkins, a daughter of Sir H. Thompson, also addressed the meeting. Mr. G. B. Morgan, J.P., the senior surgeon to the Sunderland Infirmary, moved a resolution, which was unanimously carried, proposing that the district nursing committee should affiliate with the Queen Victoria Jubilee Institute for Nurses. It is difficult to over-estimate the enormous amount of good done by the various district nursing associations in the north of England, almost all the large towns and many of the country districts deriving good from their most laudable efforts.

Typhoid fever from eating Uncooked Mussels.

Mr. J. Cromie reported last week to a meeting of the Blyth port sanitary authority a number of cases of typhoid fever in the district the result of eating uncooked mussels collected from beds in close proximity to the spot where the sewage from the hospital for infectious diseases ran into the river. This is not the first time Mr. Cromie has drawn attention to typhoid fever contracted in a similar way. The authority passed a resolution ordering that a warning should be posted pointing out the danger of eating mussels taken from the River Blyth—the least it could do under the circumstances.

New Site for the Royal Infirmary, Newcastle-upon-Tyne.

The freemen of Newcastle, of whom Mr. John Hall is one, agreed a few days ago to give to the governors of the Royal Infirmary a site of eight acres on the Leazes as a free gift. This is the site which the governors of the infirmary wish to acquire, and the one which, in their opinion, will be the most useful for their purpose. The freemen have always shown a most sympathetic spirit towards the Royal Infirmary in its endeavour to procure a new site, and this magnificent gift, valued at some £80,000, is a liberal response on their part to the princely offer of Mr. J. Hall to expend £100,000 of his own money in building a new infirmary. Unfortunately, however, while the herbage only belongs to the freemen the soil is the property of the corporation, and therefore the site cannot be acquired without the aid of the corporation. If that were given an act of parliament would still be required to enable the transfer of the land to the infirmary. On Oct. 13th the Town Moor Management Committee, to whom the petition from the infirmary for a site had been referred by the corporation, met, and as after discussion it was found that there was a pretty equal division of feeling, one section proposing that ten acres on the Leazes and the other that ten acres of the Bull Park should be given for the purpose, it was finally resolved that the committee should recommend the council to give one or other of these two sites, leaving it to the council to make a selection. On Monday last the council met and after a long and animated discussion separated without determining the question, which is again to be discussed on Oct. 28th.

Oct. 19th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Aberdeen.

THE medical, arts, and agricultural classes opened for the winter session on Oct. 13th. At the English literature class Professor Grierson devoted a portion of the opening lecture to a reply to remarks by a writer in THE LANCET on the "Decline of the Scottish Universities." The University court have by a majority resolved that in the present state of the finances they are unable to hand over to the town council the buildings fronting Broad-street which are intended to be removed. The completion of the new south wing of the buildings extension at Marischal College

Digitized by Google

will leave the committee with a deficit of perhaps £20,000, and until further funds are raised no further buildings can be undertaken. Hence the desire of the court not to sacrifice in the meantime the rents of the properties mentioned. Hopes, however, are entertained that by a further contribution from Government and private subscriptions the whole scheme will ultimately be carried out, including the widening of Broad-street and the removal of the old, and the erection of a new, Greyfriars church.

New Hospital Buildings in Aberdeen.

The new medical block at Aberdeen Royal Infirmary—the last instalment of the Jubilee extension scheme of 1887—is now completed and was opened for patients on Monday last, Oct. 18th. It is a granite building, four storeys in height, with a frontage of 200 feet to Woolmanhill, and will accommodate 94 patients in all, while the total cost of the block has been about £15,000. On each of the ground, first, and second floors are two wards for male and female cases respectively of the ordinary type, and the top storey is adapted for eight erysipelas patients with two isolation beds. On the first three floors, in the central portion, are the necessary rooms for the work of the wards, and the corridors are eight feet wide. The wards and corridors are floored with Acme patent wood blocks—which have not been used so far north before—and the windows are on Nap's revolving principle. The interior of the walls throughout is finished with enamel and all angles have been rounded. The water-closet, slop, and other sinks are from Doulton and Co., of London, and are of special make suitable for hospital purposes. The heating and ventilation are on the Sturtevant system, and in the wards are Teake's barless grates. On the west side of the building on the upper floors are balconies with wrought-iron railing for airing purposes. At the end of each of the male wards is a separate sitting- and smoking-room and at the end of the female wards a sitting-room. The Otis Elevator Co., of London, have supplied a hydraulic lift which is fitted with safety grip chisels. The whole of the hot and cold water-pipes in connexion with the building are of copper. The stairs are formed of stone and the landings as well as the balconies are paved with Peake's tiles. A tunnel runs under the hospital central yard and connects with the surgical block and mortuary. The building is lighted by electricity and telephonic communication will be introduced. Chorlton and Co.'s patent cots and other hospital furnishings of modern type have been provided under the supervision of Mr. Charles Angus, M.B., C.M. Aberd., the new medical superintendent. The new convalescent hospital at Pitfodels, Cults, about four miles from the city, to be worked in connexion with the Royal Infirmary, and previously referred to in THE LANCET, is also completed, and was likewise opened for patients in the course of this week. It is a granite building of two floors in front and three floors in the rear, and will accommodate twenty-six patients besides the requisite nurses, &c. Water is procured from Aberdeen city water-supply.

New Medical Scholarship at Aberdeen University.

The Fence Scholarship in the Westminster Medical School has now been transferred to Aberdeen through the agency of Dr. Charles Phillips, the well-known writer on pharmacology, whose name the foundation will bear. The annual value is £40, and the scholarship will be awarded in connexion with the materia medica department. The thanks of Aberdeen University Court have been voted to Dr. Phillips and the London trustees.

University of Glasgow.

The Medical Session was opened on the 14th inst. There was no general address to the students, and the only noteworthy feature of the commencing session was the introductory lecture delivered by Dr. Stockman, the newly-appointed Professor of Materia Medica and Therapeutics. Dr. Stockman discussed the relationships between pharmacology and therapeutics and advocated the combined study of pharmacological investigation and clinical observation. He was introduced to the students by Dr. Gairdner, and met with a cordial reception. At a meeting of the University Court on the 15th inst, a communication from Dr. James Finlayson and Dr. Hector Cameron was read offering to the University a replica of a portrait of Lord Lister painted in 1895. The Court accepted the portrait with thanks to the donors. Leave of absence for the winter session was granted to Professor Joseph Coats on account of ill-health. Professor Coats has been much benefited by his residence during the summer in the Channel Islands, but it is deemed advisable that he shall have a further rest, and he is to spend the winter in New Zealand. The University Court have approved of the suggestions made by the General Council that the conditions under which "honours" are granted to graduates in the medical Faculty shall be printed in the University Calendar. They have also accepted the offer of the Bellahouston trustees to provide a certain number of gold medals annually to be awarded to worthy candidates for the degree of M.D. Professor Gairdner and Mr. William Crum have been appointed to represent the university on the board of managers of the Victoria Infirmary. The resignation by Dr. C. O. Hawthorne, of the Lectureship in Materia Medica and Therapeutics in Queen Margaret College, has been intimated to the University Court.

Medical Appointments.

Mr. Albert A. Gray, M.D. Glasg., has been elected assistant pathologist to the Glasgow Cancer Hospital. Mr. John A. Kennedy, M.A., M.D. Glasg., has been appointed visiting physician to the convalescent home of the Royal Infirmary, Glasgow. Mr. J. C. G. Duffus, M.A., M.D. Aberd., has resigned his position as assistant surgeon to the Royal Infirmary, Glasgow. The in-door and out-door house-surgeonships to the Glasgow Maternity Hospital are vacant. It has been decided by the managers of the Glasgow Samaritan Hospital to appoint three assistant medical officers to the "Agnes Barr" Dispensary.

Western Infirmary, Glasgow.

The atmosphere of the infirmary is at present in a somewhat stormy condition. The resignation by Dr. Gavin P. Tennent of his position as one of the visiting physicians was followed by a resolution of the managers to appoint an additional surgeon and not to fill up the vacancy created on the medical side by Dr. Tennent's retirement. This resolution was accompanied by a plan for the redistribution of the wards, and some of the features of this redistribution have given umbrage to certain members of the staff. The friction has, indeed, been so extreme that rumour confidently credits one of the leading surgeons with the determination to transfer his services to another hospital should the proposal to reduce the number of beds under his care be carried into execution. The new arrangements also contemplate the allotment of a certain number of beds to "the clinical teaching of materia medica and therapeutics." It is understood that this decision is the result of pressure from the Glasgow University authorities, who not unnaturally desire to secure for the newly appointed professor of materia medica opportunities for clinical observation. What the public will think of an open proclamation to devote hospital beds which are supposed to be supported for the relief and cure of patients to "the clinical teaching of materia medica and therapeutics" remains to be seen. For the position of additional visiting surgeon created by the decision of the managers there are several candidates, but the contest is understood to lie between Dr. J. Crawford Renton and Dr. T. Kennedy Dalziel, each of whom is already an assistant surgeon to the infirmary.

Oct. 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Meath Hospital, Dublin.

THE address introductory to the medical session was delivered on the 11th inst. at the Meath Hospital by Sir Philip Smyly, and dealt mainly with the work which had been accomplished by the General Medical Council in improving the medical curriculum. Lord Holmpatrick filled the chair, the vote of thanks to the lecturer was proposed by Viscount Powerscourt, while the second chair was taken by Sir George Duffey, the President of the Royal College of Physicians of Ireland.

Death of Mr. Stamer O'Grady.

Much regret is expressed by the medical profession here and by the public at the sudden death of Mr. Edward Stamer O'Grady, which took place in the evening of the 18th inst. The deceased was a Bachelor in Medicine of the University of Dublin and a Fellow of the Royal College of Surgeons.

Digitized by Google

in Ireland. He succeeded the late Mr. Butcher as surgeon to Mercer's Hospital, and was for many years a lecturer on surgical anatomy at the Ledwich School of Medicine, and a member of the Court of Examiners of the Royal College of Surgeons. At a time when the clinical class of Mercer's Hospital was the largest in Ireland Mr. O'Grady was one of its most brilliant and successful teachers.

Lunatics in Workhouses.

At the last meeting of the Celbridge board of guardians Colonel Sir Gerald Dease, who was in the chair, spoke very strongly in favour of a resolution as to the desirability of provision being made in the Local Government Bill of next session for the removal of all lunatics and idiots from the workhouses in Ireland to the asylums.

The Royal College of Physicians of Ireland.

The annual meeting of the Royal College of Physicians of Ireland took place on St. Luke's Day, Oct. 18th, when the officers of the college for the ensuing year were elected. In the evening the annual banquet of the President and Fellows was held in the college hall.

The Belfast Workhouse.

At the usual weekly meeting of the Belfast board of guardians, held on Oct. 12th, the half-yearly report of Mr. Agnew, inspector of the Local Government Board, was presented, and, as one of the guardians said, it would seem from it "that the whole institution there was unfit for human habitation." Mr. Agnew recommended the substitution of hair for straw mattresses. On the day of his inspection he found the bread and beef were very unsatisfactory, the former being not properly ovened and the latter of inferior quality and almost devoid of fat. He took exception to the ventilation; the drainage from the separation and lunatic departments was in a very unsatisfactory state, and should be remedied at once; the water-closets in the separation department were unsatisfactory, those in the infirmary were in a disgraceful state owing to the want of water, and those in the yards for the use of the lunatics were also in a most insanitary state from the same cause. With regard to the pauper attendants Mr. Agnew said he understood from the officers that they were in the habit of soliciting money from the friends of the patients, and he suggested that a few temporary nurses should be appointed with a view of removing the pauper nurses from attendance on the sick. He had further to remark that some of these women drank and used foul language to visitors who did not respond to their demands for money. The bath-room he reported as being in a discreditable state. The mortality from typhoid fever during last year in the union hospital was only slightly over 8 per cent., which was very low. A committee was appointed to consider this report.

The Typhoid Fever Epidemic in Belfast.

The typhoid fever epidemic (the cases of which are not localised in one district, but scattered all over the city) is slightly diminishing, and the public are still very much exercised as to its origin. At the last monthly meeting of the City Corporation some members hinted that it might be due to the water-supply, and as a result the water commissioners have obtained a report, dated Oct. 13th, from Dr. Frankland, of Birmingham (who recently analysed very fully the Belfast water), on this subject. He is of opinion: 1. That whilst the present sources of the Belfast supply are undoubtedly exposed to a certain amount of contamination in consequence of the gathering-grounds being to some extent populated and under cultivation, the best-known methods for rendering this water safe for consumption have been adopted. The supply is, in fact, provided with most extensive storage reservoirs and with magnificent filtration works. 2. That bacteriological evidence shows that these methods of purification, if properly attended to, furnish most effective barriers against the passage of disease-producing bacteria to the water consumer. 3. That towns which, like London, are supplied with water derived from enormously more populated and cultivated gathering-grounds, but which water is submitted to these same methods of purification, enjoy the most remarkable freedom from typhoid fever. 4. That in view of these facts it appears in the highest degree improbable that the typhoid fever epidemic now prevalent in Belfast should be chargeable to the water as sent out to the consumer. 5. That in view of the duplex character of the supply, a water-origin of the outbreak would almost certainly be betrayed by its general limitation to one of the two water areas of which Belfast is composed. 6. That simultaneous outbursts of typhoid fever should have taken place in outlying districts dependent on the same supply. 7. That the grave dangers of domestic cisterns require careful consideration, with a view to their use for drinking purposes being discontinued, and that taps on the rising main be provided in all houses. It was stated at a meeting of the Public Health Committee, held on Oct. 14th, that the water referred to and condemned at the previous meeting turned out on investigation not to be Cromac water, but had its source in an old-fashioned surface well in no way connected with the celebrated Cromac springs.

The Belfast Hospital for Sick Children.

Mr. W. G. Mackenzie has been appointed consulting surgeon, Dr. T. S. Kirk surgeon, and Dr. Lynass assistant surgeon to this hospital.

Opening of the Winter Session at Queen's College, Belfast.

Lectures in the Medical Faculty at Queen's College, Belfast, began on Oct. 19th, when the various professors met their classes. At the Royal Hospital the session was inaugurated on the same day by an introductory address from Dr. Lorrain Smith, the pathologist to the hospital, on the Value of the Facts Observed in Medicine.

Trained Nurses in Irish Union Hospitals.

At the last meeting of the Clonmel guardians, Mr. R. Bagwell said that Dr. Sheehan, Roman Catholic Bishop of Waterford, proposed to send to the Union Hospital a trained nurse from a London hospital, who would instruct the nuns and attendants and all other persons concerned. It would be no expense to the ratepayers to have her. She had been selected by persons who were connected with the movement generally in Ireland. He (Mr. Bagwell) thought it a step in the right direction and proposed a resolution approving of a trained nurse, nominated by the Right Reverend Dr. Sheehan being accommodated on the union premises on the understanding that the guardians shall not be responsible for any part of the expense. The resolution was carried and the guardians also expressed their thanks to the Bishop for his kind action in the matter.

Oct. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Advances in Radiography.

M. DOYEN has been enabled by means of the x rays to determine the site and shape of a dilatation of the œsophagus, and M. Radiguet has made an admirable print from the negative thus obtained. The method of procedure is as follows. The œsophagus is first explored with an olive-headed metallic sound, and then with two or three elastic hollow sounds filled with mercury, which are photographed *in situ*, their place having been first observed by the fluorescent screen. By using a sound which terminates in a slender pocket of indiarubber filled with mercury it is also easy to determine the size and shape of œsophageal strictures.

Intravenous Injections of Sea Water.

At a recent meeting of the Biological Society M. Quinton mentioned that he preferred injections of sea water to those of salted serum. As a consequence of his researches in evolution presented to the Academy of Sciences he has been led to suppose that "*le milieu intérieur des organismes élevés (mammifère, oiseaux) devait être un milieu marin.*" The learned writer means by this that as all the higher organisms, according to the teachings of evolution, have ascended from a less highly organised marine ancestry the more nearly that the conditions under which their cells grow ontogenetically, approximate to the conditions of the phylogeny the better it is for them. According to this hypothesis the liquid which bathes all the cells of the individual ought to be chemically similar to sea water. To confirm this theory four sets of experiments have been made at the College of France in the laboratory of M. F. Franck. The first series of which M. Quinton read an account consisted in bleeding an animal to such an extent that death would have inevitably followed had the animal been left alone. The animal in question thus placed under

Digitized by Google

conditions barely compatible with life, and as a consequence specially liable to be affected by any toxic condition, was then given an intravenous injection of sea water. The dogs experimented on not only survived but recovered with remarkable quickness, and the first dog, some ten days after the operation, showed as tested by the colorimeter a larger proportion of hæmoglobin than before the bleeding. Another dog in which the number of corpuscles fell from 6,800,000 to 2,900,000 per cubic millimetre after the bleeding was attacked by a purulent infection, but showed after an injection of sea water, and probably as a consequence of its fight against the septicæmia, a remarkable degree of leucocytosis. M. Quinton thinks that artificial serum only enjoys the reputation it does on account of its holding in suspension the same salts which are constituents of sea water, and that sea water is physiologically superior. Further experiments will, however, have to be made.

The Congress of Surgery.

The eleventh congress of the French Association of Surgery was opened on Oct. 18th in the great amphitheatre of the Faculty of Medicine at Paris under the Presidency of Professor Gross, of Nancy, a large number of French, Belgian, and Swiss surgeons being present. Professor Gross made an important speech in which he passed in review all the recent victories of science, and referred particularly to the services which the discovery of the Roentgen rays had rendered to medicine and surgery. This medium, as Professor Ollier remarked, allowed one to make a veritable necropsy of the skeleton in the living being. M. Poncet, of Lyons, read a paper upon Botryomycosis in Human Beings, in which he argued that certain papillary tumours in man were identical with the botryomycosis caused by a fungus which brings about complications in the castration of horses. M. Berger read a paper upon Epithelioma of the Neck having a Branchial Origin, and mentioned certain aberrant epithelomata of the thyroid body. M. Lavise, of Brussels, read a communication upon the Treatment of Hernia, and M. Demous, of Bordeaux, one upon Contusions of the Abdomen. The Congress lasts for a week, and very important communications are announced by M. Doyen, M. Calot, M. Tuffier, M. Le Dentu, M. Jonnesco, and others.

The Etiology of Cirrhosis in the Intemperate.

In the Academy of Medicine M. Vallin adversely criticised the views expressed by M. Lancereaux in a communication made to the Academy some time ago,[1] views which M. Vallin considered might have a prejudicial effect on an important branch of industry. M. Lancereaux has found that cirrhosis results from the excessive use of wine, say, from 2 to 6 litres (i.e., from 3½ to 10½ pints), continued for several years, and he quoted in support of his assertion statistics of 210 cases, in 68 of which wine only was the beverage taken in excess, while in 120 both wine and spirits were so taken. M. Lancereaux, in fact, attributed cirrhosis to the use of wine rather than to the use of spirits, the real source of mischief, in his opinion, being the salts of potash. He administered bisulphite of potash for long periods of time to rabbits, guinea-pigs, and dogs, the doses varying from 2 to 6 grammes—i.e., from 30 to 90 grains—and he found when the animals were killed after the lapse of sixteen or eighteen months that they suffered from cirrhosis in all stages. These facts led him to believe that the "plastering" of wine conduces to cirrhosis, and he accordingly urged the prohibition of "plastering." M. Vallin, however, considers that before legislating on the subject it is necessary to have confirmation of the views held by M. Lancereaux. In the first place, the experiments upon which he relies are open to criticism, for the daily dose of 2 grammes of bisulphite of potash given to a rabbit corresponds to a daily dose of 60 grammes (i.e., 2¼ oz.) for an adult man, a quantity which seems excessive; and, moreover, beer and gin, although they cause cirrhosis, only contain a small amount of salts of potash. It must also be remembered that the wine-drinkers quoted by M. Lancereaux imbibe with the wine a quantity of alcohol corresponding to 100 grammes of absolute alcohol (= 260 grammes of brandy) per litre of wine, and it is quite possible that such doses of alcohol might produce the hepatic lesions mentioned by M. Lancereaux, altogether without reference to the salts of potash. It would therefore be advisable in the first instance to collect statistics showing the proportion of cirrhotic cases in countries (the French colonies, for instance) where the use of wine is quite unknown. Aeration of the must is available as a means of preservation instead of "plastering," but very precise statistics would be required to justify such a revolution in the wine trade. M. Lancereaux replied to M. Vallin that in explaining the etiology of cirrhosis he relied on obvious clinical facts. Pathological observations show that the livers of men who drink three litres (five and a quarter pints) of wine over a period of several years are enlarged and merely hyperæmic; they will pass into cirrhosis, which is no more than a final stage. In spirit-drinkers, on the other hand, the liver is fatty and has no "bi-venous" lesions. Cirrhosis, moreover, is unusual in the colonies where the use of wine is unknown. In proof of the injurious effects of plastered wines he mentioned that cirrhosis is comparatively rare in Burgundy, where the wines in use are not plastered, but it is common enough in Paris. M. Laborde said that he did not entirely agree with M. Lancereaux, and asked permission to submit on a future occasion the results of some investigations which he had undertaken.

Oct. 19th.

[1] THE LANCET, Sept. 18th, 1897, p. 748.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The International Conference on Leprosy.

THE International Conference on Leprosy was formally opened on Oct. 11th in the large hall of the Imperial Health Office, Professor Lassar, as President of the executive committee, being in the chair, the other members of the committee being Professor Virchow, Dr. Armauer Hansen, of Bergen (Norway), Professor Besnier, of Paris, and Dr. Ehlers, of Copenhagen. A great many leading dermatologists and hygienists took part in the proceedings. The opening ceremony was attended by representatives of the Government, the university, the Berlin Municipality, the army medical staff, and the Berlin medical societies. Professor Lassar delivered an inaugural address in which, after welcoming the visitors, especially those who had come from foreign countries, he said that the objects of the conference were, firstly, to afford the members an opportunity of discussing questions concerning leprosy, and, secondly, to draw the attention of the various Governments to these questions. Professor Virchow was then elected President, and Professor Lassar, Professor Besnier, and Dr. Ehlers vice-presidents of the Conference. Count Posadowsky, Secretary of State for Home Affairs, thereupon made a complimentary speech, in the course of which he stated that the proceedings of the Conference were regarded with great interest by the Government and that the advice given by the eminent men who had now assembled in Berlin would undoubtedly be followed in the struggle against this terrible disease. The first address was delivered by Dr. Hansen, who was received with loud applause. He emphasised the necessity of isolation of lepers, a measure which he said was as much in the interest of the patients as in that of the community at large. It has been found by experience in Norway that lepers who have been placed in special homes regain the power of doing work, and in this way once more become useful members of society. Leprosy being an affection of many years' duration this fact should not be neglected. In Dr. Hansen's opinion the efforts of Unna, Carasquilla and Danielsen to cure leprosy by means of drugs or by serum treatment have been quite ineffectual. Leprosy diminishes under the influence of strict isolation and increases again when isolation ceases to be enforced. He is hopeful that the disease will have disappeared from Norway in the course of the century now approaching. In the cases where isolation in special asylums is not possible the patient should at least have a room to himself, together with bedding and table utensils set apart for his use. Cleanliness is the best safeguard against infection, and it has been found in America that the cleanly habits of the people had the effect of rendering the spread of leprosy much slower than in the majority of European countries. The hypothesis that leprosy might be due to hereditary influence is erroneous. — In the ensuing discussion Professor Dehio, of Dorpat, stated that the principles which were in force in Norway were also followed in Russia; isolation, however, was not compulsory, but voluntary on the part of the patients. The effects of this system were very satisfactory.—The French delegate, Professor Besnier, of

Digitized by Google

Paris, was of opinion that careful surveillance of lepers and the taking of precautions with a view to protect their families were sufficient and that compulsory isolation was not necessary.—The further proceedings of the conference will be reported in my next letter.

The Berlin Dermatological Society invited the members of the conference to a meeting held in their honour on the evening of Oct. 13th. After the usual introductory courtesies Professor Lassar delivered an address on public hygiene and its relations to venereal diseases. Professor Kaposi and Professor Neumann, of Vienna, and Professor Besnier, of Paris were at the same time elected honorary members of the society.

The German Association of Naturalists and Medical Men.

The meeting of this association, which took place in the last week of September in Brunswick, was attended by fewer medical men than on any previous occasion. This fact is partly due to the International Congress in Moscow having attracted an enormous number of German visitors, who naturally felt themselves disinclined to take part in a second great scientific meeting held so soon afterwards. Another cause of the falling-off in the attendance is the great number of congresses of the special branches of medicine. The *Deutsche Medicinische Wochenschrift* accordingly once more suggests that the general congresses of all branches of medicine should be held only every second year, so that the intervening years will be free for special congresses. The next meeting will be held at Düsseldorf in Rhenish Prussia.

The Practitioners' Association.

The last meeting of the Practitioners' Association was held in Eisenach, and as it happened to be the twenty-fifth anniversary the introductory proceedings were marked by more ceremony than usual. The principal subject of discussion was the course to be adopted for the repression of unqualified practice. Fines for unqualified practice were abolished in Germany as far back as 1867, and in no small degree through the efforts of a great combination of medical men who believed that the public had become sensible enough to abstain from consulting quacks. This opinion, however, was not justified by the results, for quacks have greatly increased in number during recent years, and the harm done by them to the medical profession and the public is immense. Dr. Leut, of Cologne, quoted some interesting figures showing the extension of quackery, and after his address, which was followed by an animated discussion, the meeting almost unanimously adopted the following resolutions:—(1) That the abolition of the laws against unqualified practice has done great harm to the medical profession and to the public; (2) that in consequence of unqualified persons engaging in medical practice with impunity the public fail to distinguish between qualified and unqualified men; and (3) that the laws regulating the practice of medicine are in need of alteration. The second subject of discussion was the appointment of medical officers for the inspection of schools. The meeting unanimously approved of the appointment of medical men in connexion with schools in order to control the hygienic condition of the classrooms, to take notice of the health of the children, and to prevent over-pressure. The other subjects on the programme were of minor interest.

Oct. 17th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Lakes as a Source of Drinking-water.

THE north Italian towns, as a rule, are badly supplied with drinking-water pure in quality and abundant in quantity, Milan alone, for example, being a perennial sufferer from that cause, and periodically agitated by controversy as to which of her (at least) five projects for the introduction of "acqua potabile" she should end by adopting. Meanwhile, her Swiss neighbour has been furnishing her with a suggestion she would do well to consider. For some time past the Confederation, through some of its most eminent hygienists, has been experimenting on the Lake of Geneva as to whether by going deep enough it would not be practicable to draw from that sheet of water a constant supply of "acqua potabile" for the many towns upon its banks. The other day a considerable party of medical men, sanitary officers, and public-minded citizens started on board a steamer from Lausanne to make a final experiment in the series that has for some time been in progress. They dropped anchor about 700 metres from the shore of Lutry, at a point where the lake is 120 metres deep. Thereafter they let down a number of tubes and drew up water from a depth of 100 metres. On trial this water was found to be excellent as a beverage, and on subsequent analysis it proved to be absolutely pure. Now, it is being asked, why should not Milan make similar experiments on Lake Como quite near, and if they turned out as satisfactory as those on the Lake of Geneva, why should she not proceed to utilise the water for her ever-increasing population and for her large contingent of the travelling world? Lake Como has a depth of 416 metres between Bellagio and Varenna and one of 150 metres between Bellagio and Cadenabbia. Its superficial space, as a whole, is 143 square kilometres and its waters are fed by thirty-seven mountain torrents and twenty-one streams. As the Swiss Commission seems to have made out, you have only to go deep enough in such extensive inland seas as the greater lakes on either side of the Alps to find water deliciously fresh, absolutely untainted, and almost illimitably abundant. As already indicated, in Lake Como, well-nigh at her door, Milan possesses such a natural reservoir. Assuredly the Swiss experiment is well worth imitation, and if successful might be followed by other north Italian cities in proximity to the Lago Maggiore and Lago di Garda. Milan in an especial degree is called upon to initiate some such enterprise. More than the rest of Italy she is in constant dread that the contract for carrying our Indian mails and travelling public by the Brindisi route should lapse, other competitors for that lucrative undertaking continuing to tender offers peculiarly tempting. Among the objections to Italy retaining the contract are the grave inconveniences of the railway service at Brindisi itself and (to say nothing of the frequent luggage robberies) the insanitary state of the halting-places along the route, for instance, Bologna, and in a graver degree Milan from her very bad water-supply. No time should be lost, therefore, in minimising, on at least one important side, the objections which militate to her disadvantage—objections which if persistently ignored may cost Italy a source of revenue which she has enjoyed for a quarter of a century and deprive the Lombard capital of resources not to be replaced.

The Yellow Fever in New Orleans and the Italians.

From Italian correspondents residing in New Orleans it would appear that the epidemic of yellow fever in that city and neighbourhood shows little sign of diminution. One cause of its permanence is the refusal of the Italian population to report incipient cases to the sanitary authorities. "Our compatriots," says one correspondent, "more than any other part of the community are stubbornly contumacious (*restii*) in thwarting the provisions of the Commission of Hygiene," and the disease has gained ground in the Italian quarter proportionally. Philip-street represents the core of that quarter, and there the sanitary inspectors have had to invoke the police so as by main force to effect an entrance into houses where the inmates were known to be dying or dead from yellow fever. Cases are cited by the correspondents above referred to, such, for instance, as that of a young woman, whose father had died six days before from the fever, and who, struck down by the malady, was herself almost at the point of death. On the arrival of the sanitary officers her relatives, suspecting their object, rolled her up in a sheet and tried to smuggle her out of the house and convey her to some other place. The attempt was frustrated in the nick of time; the dying girl was rescued by the officers, and the rest of the family accommodated in the public "lazzaretto." Such incidents, familiar enough in Naples during a cholera epidemic, strike a jarring note when reported from such a city as New Orleans and tend to explain the extreme unpopularity of the Italian element in its population.

Oct. 18th.

AMBULANCE COMPETITION IN GLAMORGANSHIRE.—The annual ambulance competition, held under the auspices of the Glamorganshire County Council, took place at Pontypridd on Oct. 9th. Seven teams competed. The first prize was won by the Llancarvan team. The judges were Dr. Williams, of Cardiff, and Dr. Thomas, of Ystrad.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated:—

Monday, Oct. 11th:

Anatomy and Physiology.—Samuel Ernest Atkinson, Benjamin Holroyd, James Ebor Bolton, Ernest John Crawshaw, and Talbot Carter Mitchell, Yorkshire College, Leeds; Clifford Price, University College, Cardiff, and St. Mary's Hospital; Miguel Arango, Bogota University, Columbia, and St. Mary's Hospital; Robert James Harbinson and William Stewart Dickie, St. Mungo's College, Glasgow; William Matthew Hunter, Queen's College, Belfast; Leonard Augustine Moore, University College, Bristol; Matthew Frederick Foulds, Owens College, Manchester; George Archibald Carter, Surgeons Hall, Edinburgh; Harold Myrie Cory, Mason College, Birmingham; Frank Gray Quinby, University College, Liverpool; Robert Edward Hodgson, St. Mary's Hospital; John Valérie, St. Bartholomew's Hospital; and Charles Ellard Van Rooyan, Medical College, Ceylon.

Seventeen gentlemen were referred back to their professional studies for three months and one for six months.

Tuesday, Oct 12th:

Anatomy and Physiology.—Thomas Young, Leonard Edgar Whitaker, Gerald William Stone, and Walter Ernest Llewelyn Davies, St. Bartholomew's Hospital; John Stephenson Clarke, Cambridge University and St. Thomas's Hospital; William Edward Denniston and Charles John Ernest Edmonds, St. Thomas's Hospital; Edward Michael William Hearn and George Stafford Ward, London Hospital; Clayton Alexander Francis Hingston and Henry Vernon Swindale, Middlesex Hospital; William Johnson, Guy's Hospital and Mr. Cooke's School of Anatomy and Physiology; Kenneth Vincent Trubshaw and Frank Cordeux Wetherell, Guy's Hospital; and James Ward Lawson, Charing-cross Hospital.

Twenty-one gentlemen were referred back to their professional studies for three months.

Wednesday, Oct. 13th:

Anatomy and Physiology.—Hector Alfred Colwell, Henry Norman Marrett, Edward Vaughan Lindsey, Robert Culverwell Bowden, Digby Sayer Sandiland, and Reginald Bigg, St. Bartholomew's Hospital; Charles Montague Heanley, St. George's Hospital; Joseph Clement Justinian da Silva, Arthur Cedric Lewis, and Hugh Arthur Higgins, Guy's Hospital; Henry Brookes Carr, Firth College, Sheffield, and Guy's Hospital; Gerard Lyne Parsons, Westminster Hospital and Mr. Cooke's School of Anatomy and Physiology; Wilfred Alexander Steen, Gerald Griffin, Eric McLeod Perkins, and Frank Challans, London Hospital; and Ernest Henry Hogg, Middlesex Hospital.

Nineteen gentlemen were referred back to their professional studies for three months.

Thursday, Oct. 14th:

Anatomy and Physiology.—Edward Percival Mitchell, Guy's Hospital; Percy Douglas Hunter and Herbert Vale Bagshawe, Guy's Hospital and Mr. Cooke's School of Anatomy and Physiology; Cecil Hugues Francis-Williams, St. George's Hospital; Walter Seymour Armstrong, St. George's Hospital and Mr. Cooke's School of Anatomy and Physiology; Francis Goding Bowen, George Orissa Taylor, and Thomas Frederick Gisborne Mayer, London Hospital; Hugh Edward Drummond Lloyd, Charles Fisher, and John Ellis Griffith, St. Bartholomew's Hospital; Francisco José Gómez, King's College, London; Cecil Irving Grabham and Edward Henry Bullen, St. Mary's Hospital; Edward Cecil Foster, University College, London; George Osborne Hughes, University of Virginia and Mr. Cooke's School of Anatomy and Physiology; and Robert James Johnstone, Queen's College, Belfast.

Anatomy only.—Elijah Richard Lockwood Thomas, London Hospital; Orme Sterling Kellett, London Hospital and Mr. Cooke's School of Anatomy and Physiology; and Frederick Aylmer Hort, Middlesex Hospital and Mr. Cooke's School of Anatomy and Physiology.

Physiology only.—Alexander Farrington, St. Bartholomew's Hospital; Henry Joseph Butler, St. George's Hospital; and Herbert Charles, Middlesex Hospital.

Five gentlemen were referred back to their professional studies in both subjects, and two in Physiology only for three months.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations and having conformed to the by-laws and regulations, have been admitted Members of the College:—

Welch, Walter Barrows, L.S.A. Lond., St. Bartholomew's Hospital.
Wood, Charles Rawdon, M.B. and B.S. Durh., University of Durham and University College Hospital.

From the report of the council about to be issued to the Fellows and Members of the College it appears that the names of 34 Fellows and 230 Members have been removed from the list published in the College Calendar during the past collegiate year in consequence of death. During the past year the supply of new books and periodicals has been well kept up. Several old books have been presented by Mr. R. H. Lucy, F.R.C.S. Eng. Mr. Longmore has presented an engraving of Bransby Cooper which had formerly belonged to Sir Thomas Longmore. During the past year the library has been open on 271 days, and the number of readers has been 10,965.

AT a meeting of the Lincoln City Council held on Oct. 15th it was agreed that for the coming year Dr. John T. Collier should be mayor. The mayor-elect is a representative of the Middle Ward in the City Council.

NEW UNIVERSITY HALL AT BANGOR.—The new county school for girls, built at a cost of £2320, and the university hall for women students, upon which £5200 have been expended, were opened at Bangor on Oct. 9th, when addresses were delivered by Dr. Isambard Owen, Mr. Acland, M.P., and Mr. T. E. Ellis, M.P.

BRISTOL CONVALESCENT HOME.—The Mayor of Bristol has received £21,500 towards the proposed Convalescent Home for Bristol. This, with the conditional promises, makes a total of £64,500. The sum of £5500 now remains to be subscribed in order to make up the £70,000 required for the institution, and this amount must be received by Dec. 1st if the conditional subscriptions are to be secured. The fund has received such support from the citizens that it is confidently hoped the amount will be forthcoming.

A WOKING druggist was summoned at Guildford last week by the Surrey County Council for selling "Gregory powder" which was not of the nature and substance asked for by the purchaser. A label on the package stated that it was prepared according to the original recipe of Dr. Gregory. As a matter of fact carbonate of magnesia had been substituted for the more expensive oxide. For the defence it was stated that the carbonate had the same effect therapeutically as the oxide, and medical evidence was called to prove this. The Bench held that the article sold was not to the detriment of the purchaser and dismissed the case.

FOREIGN UNIVERSITY INTELLIGENCE.—*Budapest:* The charge of the Surgical Clinic has been temporarily taken over by Professor Dollinger in place of the late Professor Kovács.—*Cracow:* Dr. Obalinski has been appointed Professor of Surgery.—*Königsberg:* Dr. Ernst Leutert has qualified as *privat-docent* in Otology.—*Lemberg:* Dr. Rydygier, of Cracow, has been appointed to the chair of Surgery.—*Naples:* Dr. Donato Greco has qualified as *privat-docent* in Dermatology.—*Zürich:* Dr. Justus Gaule, Professor of Physiology, has been obliged to take leave of absence on account of the state of his health, and Dr. von Frey has been invited to go from Leipzig to supply his place.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—The medical school at the University College was opened on Oct. 4th, an increased number of students enrolling in the books. This session the teaching staff has been increased by the appointment of Dr. Alfred William Sheen as demonstrator of anatomy, and of Mr. S. C. Mahalanobis, B.Sc., as demonstrator of physiology. Professor Francis Dixon commenced his first course of winter lectures at the College, and he has to face the difficult task of refilling the anatomical museum. The specimens being the private property of the late occupant of the chair have for the most part been removed, but will be more than replaced from funds placed at the disposal of the College by the generosity of Professor Alfred Hughes. In the physiological department a large work bench has been constructed at which a class of students may pursue their studies in experimental physiology; it is provided with a shaft run from an electro-motor, from which a series of revolving drums can be run independently of each other within a wide limit of speed. The following students of medicine have obtained entrance scholarships and exhibitions: William S. Hughes (Entrance Scholarship), Joseph William Evans (Glamorgan Free Studentship), David Morgan Hughes (Monmouth Free Studentship), and Arthur Edward Fiddian (Cardiff Free Studentship). A meeting of the council of this College was held in Cardiff on Oct. 13th, under the presidency of Lord Tredegar. A cordial vote of thanks was unanimously passed to Professor Hughes (the late professor of anatomy) for his gift of £350 and a series of illustrations for the anatomical museum of the College. It was stated that the Carmarthen County Council had granted a science scholarship to be tenable at the College. The Principal said that the number of students at the end of last session was 431.

THE Worshipful Company of Mercers have sent a donation of 50 guineas to the Royal Chest Hospital, City-road, E.C.

UNIVERSITY COLLEGE, BRISTOL.—The Council of University College, Bristol, have accepted the offer of Her Majesty's Commissioners for the Exhibition of 1851 to place at their disposal next year a science scholarship of the annual value of £150 tenable for two years.

MEDICAL MAGISTRATES.—Mr. J. Comyns Leach, M.D. Durh., B.Sc. Lond., of Sturminster Newton, coroner for North Dorset, has been appointed to the Commission of the Peace for the County of Dorset on the nomination of the Lord-Lieutenant.—On the recommendation of the Lord-Lieutenant of Carnarvonshire, Dr. R. Langford Jones, of Bangor, has been placed on the Commission of the Peace for the county.

EDINBURGH GRADUATES' DINNER AT BIRMINGHAM.—On Oct. 14th a large number of the graduates in medicine of the University of Edinburgh residing in the Midlands dined together at the Grand Hotel, Birmingham. Dr. Robert Saundby presided, and Dr. Thomas Chavasse occupied the vice-chair. In every way the dinner was a most enjoyable one. The toast of the evening, "The University of Edinburgh," was proposed by Dr. Saundby and drunk with enthusiasm. It was unanimously decided to form a "Midland Club of Edinburgh Graduates," the members of which will be asked to meet and dine together at least once a year. A committee, with Mr. Christopher Martin and Dr. Douglas Stanley as honorary secretaries, was appointed to make the necessary arrangements. It is hoped that not only all the medical graduates, but also those of the other faculties residing in the Midlands, will join the club which has been so successfully inaugurated.

SOCIETY FOR THE STUDY OF INEBRIETY.—At a meeting of this society held on Oct. 14th Surgeon-Major G. K. Poole, M.D. Erlang., read a paper on the Etiology of Inebriety. He presented the opinions of a large number of clergy, laymen, and medical practitioners, and also of others. With the exception of that of one medical man the testimony was affirmative of heredity as a predominant factor, and of business and domestic distress and worry as causative in a substantial proportion. Some non-medical reporters attributed up to 50 per cent. as being consequent on "doctors' orders," but Dr. Hare, Dr. Morton, Mr. Aydon Smith, Dr. Longhurst, Dr. Paramore, and the President repudiated the accusations, the President stating that not more than ½ per cent. of over 2000 cases could he trace to anything of the kind. Dr. W. Bode, of Hildesheim, stated that in January, 1900, the new German Code would come into operation for interdiction and compulsory dealing with inebriates.

FREEMASONRY.—*The Rahere Lodge No. 2546:* A meeting of the Rahere Lodge was held at Frascati's Restaurant on Oct. 12th, Bro. W. J. Walsham, W.M., in the chair. Bros. Neill and Perram were admitted to the third degree in Freemasonry; Bros. Haines, Sargant, Matthews, Miles, and Shewell to the second; and Messrs. Ellis and Auden and Surgeon Folliot, R.N., were initiated. Bro. C. O'B. Harding, of Eastbourne, and Bro P. B. T. Stubbs, of Wynberg, Cape Town, were elected joining members. A resolution of condolence was proposed by Bro. Keogh Murphy, seconded by Bro. Valerie, and passed unanimously, to Mrs. Forman on the loss of her son, Bro. G. H. Forman, wrecked in the *Aden*. A vote of one guinea to the Home for the Dying was confirmed. Fifty-one brethren with their guests afterwards dined together.—*Æsculapius Lodge:* The seventh installation meeting of the Æsculapius Lodge was held at the Café Royal, Regent-street, on Oct. 13th, the Master, Dr. Thomas Dutton, being in the chair. Mr. Edward H. Ezard, M.D., D.Sc Edin., was installed Master for the ensuing year. Mr. G. Danford Thomas, M.D. Brux., coroner for Central London, was re-elected treasurer. Mr. Thomas Dutton, M.D Durh., M.R.C.P. Edin., was appointed secretary. The auditors brought in the report of the audit committee, which showed a very good balance in the treasurer's hands. Surgeon-Major E. W. Reilly, L.R.C.P., L.R.C.S. Edin., was unanimously elected a joining member. A large number of members and visitors were present, forty-five of whom afterwards dined together and spent a very pleasant social evening.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL.—The following entrance scholarships have been awarded:—Entrance Scholarships in Arts, of the value of £50: Armin Gascoigne Vavasour Elder, Edward William Dewey, and George Arthur Jones (Pauline Scholar). Entrance Scholarships in Science, of the value of £85: Edmund de la Fosse Bond, B.A., of Keble College, Oxford, Norman J. McCaskie, B.A., of Caius College, Cambridge, and Charles John Nepean Longridge, of Owens College, Manchester.

A DEPUTATION of the Corporate and Medical Reform Committee was received on Wednesday afternoon by the President and Council of the British Medical Association, the object of the deputation being to invite the British Medical Association to take the lead in organising concerted action in favour of a certain reform programme. The deputation consisted of Dr. Hugh Woods, Dr. T. Granville Hockridge, Dr. C. Milner Browne, Dr. J. Wheeler O'Pryon, Mr. A. S. Morton, and Mr. R. B. Anderson, and was introduced by Mr. George Brown.

BRITISH MEDICAL BENEVOLENT FUND.—The British Medical Benevolent Fund has received from the executors of the late Dr. Robert Gee, of Liverpool, a bequest of £200, less duty, to be invested and added to the capital, the dividends on which are appropriated to the payment of the 107 annuitants now on the books. We regret to hear that the other branch of the fund—the Grants department—is much in need of further subscriptions or donations to enable the committee to relieve the many urgent cases consideration of which, at their last monthly meeting, they were obliged to postpone for want of funds.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors of this society was held on Oct. 13th, Dr. Pollock, vice-president, being in the chair. A new member was elected, and the deaths of four were reported. Two widows in receipt of grants had died since the last court; a fresh application for assistance from a widow for herself and daughter was read and grants were made at the rate of £50 per annum to the widow and £12 per annum to the daughter. It was resolved to distribute at the next meeting a sum of £1167 among the 48 widows, 12 orphans, and 6 recipients from the Copeland Fund. The treasurer recommended that a present of £8 should be made at Christmas to each widow, £3 to each orphan, and £5 each to those on the Copeland Fund, in all £434. The treasurer's recommendation was adopted.

SOUTH-WEST LONDON MEDICAL SOCIETY.—The first meeting of the session of this society was held at the Infirmary, Wandsworth, on Oct. 13th, under the presidency of Mr. T. A. Ives Howell. Interesting papers were read and cases shown by Dr. Smyth and Mr. Stares, medical officers of the infirmary. Dr. Smyth gave an outline of the Serum Treatment of Disease, and showed a case of Tetanus in a woman, aged sixty years, which had been successfully treated by antitoxin; also a case of Congenital Pulmonary Stenosis in a child aged four years, and a post-mortem specimen from a case of Malignant Disease of the Œsophagus penetrating into the Aorta. Mr. Stares read a practical paper on the Use of Peroxide of Hydrogen as a Dressing for Ulcers, &c.; he showed a case of advanced Progressive Muscular Atrophy, and also photographs of a case of Acromegaly, with post-mortem notes. There was, in addition, an excellent demonstration of various micro-organisms and cultures which was much appreciated. The meeting closed with votes of thanks to Mr. Neal, by whose courtesy the resources of the infirmary were placed at the disposal of the society.

PATHOLOGICAL SOCIETY OF MANCHESTER.—This society held its annual meeting on Oct. 13th, Dr. T. Harris, President, being in the chair. The officers for the ensuing year were elected, as published in our last issue, after which the time of the meeting was devoted to the consideration of card specimens. The following preparations were shown:—Dr. Ashby: (1) Congenital Syphilitic Disease of Brain; and (2) Mediastinitis. Mr. S. Bishop: Preparations illustrating Abdominal Lesions. Dr. Brooke and Mr. Lancashire: Photographs of Diseases of the Skin. Dr. Burgess: Collection of Sequestra. Professor Delépine: A series of specimens illustrating the Pathogenic Effects of Bad Milk. Dr. Dockray: (1) Experimental Calcification of Kidney; and

Digitized by Google

(2) Nephritis following Poisoning by Mercury. Dr. Fox Edwards: Specimens and Drawings of Morbid Blood Mr. T. Jones: Ruptured Bladder showing Surgical Repair. Dr. Lea: Gynæcological Specimens. Dr. Ledward: Series of Photographs. Dr. Milligan: Microscopical Preparations of Nasal, Laryngeal, and Aural Growths. Dr. Moore: Specimens illustrating forms of Lardaceous Disease. Mr. Southam: Series of Drawings illustrating Diseases of the Bladder. Dr. Peter Thompson: Ruptured Aneurysm of Left Common Iliac Artery.

ROYAL PORTSMOUTH HOSPITAL.—Assistant House Surgeon for six months. Board and residence, and an honorarium of £15 15s.

SALISBURY INFIRMARY.—Assistant House Surgeon, unmarried. Board, lodging, and washing provided.

SEAMEN'S HOSPITAL SOCIETY, "DREADNOUGHT," Greenwich, S.E.—Surgeon for Dispensary, 51, East India Dock-road. Salary £63. House Surgeon for "Dreadnought" Hospital, Greenwich. Salary £59 per annum, with board and residence. Junior House Surgeon for the Branch Hospital, Royal Albert Dock, E. Salary £50 per annum, with board and residence. Applications to the Secretary, Greenwich.

ST. GEORGE'S UNION, London.—Second Assistant Medical Officer at the Infirmary, Fulham-road, S.W., for one year. Salary £50, with board, residence, and washing. Applications to Dr. H. W. Webster at the Infirmary.

ST. THOMAS'S HOSPITAL, London, S.E.—Physician.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for one year. Salary £50 per annum, with board, residence, &c.

WEST LONDON HOSPITAL, Hammersmith-road.—Assistant Physician.

WESTERN GENERAL DISPENSARY, Marylebone-road, London.—Dispenser. Salary £120 per annum.

WREXHAM INFIRMARY AND DISPENSARY.—House Surgeon. Salary £80 per annum, with furnished rooms, board, gas, coal, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

ABRAM.—On Oct. 12th, at 106, Loudon-road, Reading, the wife of G. Stewart Abram, M.B. Cantab., M.R.C.S. Eng., of a daughter.

ALDRIDGE.—On Oct. 15th, at Hamilton House, Southampton, the wife of Norman Aldridge, M.B., C.M. Edin., of a daughter.

ARMSTRONG.—On Oct. 13th, at Southgate, the wife of A. J. M. Armstrong, M.R.C.S. Eng., L.R.C.P. Edin., of a son.

DALY.—On Oct. 16th, at Cornfield-road, Eastbourne, the wife of W. J. Daly, M.B., C.M. Glasg., of a son.

FORBES.—On Oct. 9th, at "Drumminor," Calverley Park, Tunbridge Wells, Kent, the wife of Norman Hay Forbes, of Forbes, F.R.C.S. (Exam.) Edin., L.R.C.P. Lond., M.R.C.S. Eng., of a daughter (Eilidh).

KENNEDY.—On Oct. 18th, at Burke House, Beaconsfield, Bucks, the wife of William Willoughby Kennedy, M.A., M.B. Lond., M.R.C.S., D.P.H. Camb., of a daughter.

TURNEY.—On Oct. 19th, at Portland-place, W., the wife of H. G. Turney, M.B. Oxon., F.R.C.S., of a son.

MARRIAGES.

CROWLY—SPAIN.—On Oct. 14th, at the Church of the Sacred Heart Quex-road, N.W., Daniel Crowly, M.D., Coroner, Loughrea, Co. Galway, Ireland, to Agnes Mary, second daughter of the late Lewis Spain, of Oaklands, West-end-lane, West Hampstead.

DAVOREN—BROWN.—On Oct. 14th, at St. Matthew's, Redhill, John Davoren, L.R.C.P., L.R.C.S.I., of Streatham, S.W., to Laura Madeline, eldest daughter of the late Charles R. Brown, M.D., of Eastbourne and Beckenham, Kent.

FRANCIS—USHER.—On Oct. 14th, at St. Mary's, Finchley, Harvey Francis, M.B., son of the late Swinford Francis, to Jessie, daughter of Thomas C. Usher, of Woodstock House, Hendon.

GRAY—ORR.—On Sept. 16th, at Curepipe, Mauritius, Surgeon-Captain W. Lewis Gray, son of the late Dr. Gray, of Selby, to Janet Mary Orr, daughter of the late Thomas Orr, of London.

MUSGRAVE—PRENTIS.—On Oct. 16th, at All Saints', Kensington-park, Cecil Musgrave, M.D., of Cromer, elder surviving son of the late Colonel Walter Musgrave, formerly of the Cape Mounted Rifles, H.M.'s 81st Regiment, and of the 15th Bengal Lancers, and the 5th Bengal Cavalry, to Ethel Combe, only daughter of the late Surgeon-Major Charles Prentis, B.M.S., and of Mrs. C. Prentis, 29, Colville-terrace, W.

PEAKE—JAMES.—On Oct. 14th, at the parish church, Hendon, by the Rev. C. Hose, William Harland Peake, M.D., B.S., of Marden, Kent, to Ethelne, youngest daughter of the late Robert James, Esq., and Mrs. James, of Hendon, Middlesex.

WATSON—CRICHTON.—On Oct. 13th, at Westbourne Free Church, Glasgow, Alexander Oswald Cowan Watson, Surgeon-Captain A.M.S., to Marion Macfarlane, eldest daughter of George Crichton, Montgomerie-crescent, Glasgow.

DEATHS.

BARRY.—On Oct. 12th, suddenly, at the Grand Hotel, Birmingham, aged 46, Frederick William Barry, D.Sc., F.R.S.E., of Tower House, Down, Kent, Chief Medical Inspector of Local Government Board, London.

BRADLEY.—On Oct. 18th, at Philbeach-gardens, S.W., Richard Holland Bradley, M.D., F.R.C.S., aged 77 years.

CAMERON.—On Oct. 20th, at Redcliffe-square, S.W., Hugh Cameron, L.R.C.S. Edin., late of 43, Hertford-street, Mayfair, in his 88th year.

CORNISH.—On Oct. 19th, at Corvill, Shelley-road, Worthing, Surgeon-General William Robert Cornish, C.I.E., F.R.C.S., Honorary Physician to the Queen, and late Madras Army, aged 70 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (27th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), ing's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (28th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.). London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (29th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (30th).—Royal Free (9 A.M. and 2 P.M.), Middlesex, (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (25th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. T. Churton (Leeds): Some Observations on the Localising Factors in Rheumatism and Chorea, with cases.

TUESDAY (26th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Demonstration of Microscopic Specimens showing the Infection of the Capillaries of the Brain, and Illustrating the Pathological Changes in the Liver which are caused by the Debris of the Parasites. 8.30 P.M. Papers:—Dr. S. Phillips: A Case of Calcareous Metamorphosis of Tracheal Glands, Formation of Mediastinal Abscess and Bronchial Fistula, subsequent Perforation of the Arch of the Aorta, with long-continued Hæmoptysis and Death.—Dr. G. Thin: A further Contribution towards the Pathology of the Pernicious Malarial Fevers of Sierra Leone and our knowledge of the Parasite with which they are Associated.

WEDNESDAY (27th).—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4.30 P.M Council Meeting. 5 P.M. Cases and Papers.

HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Clinical Evening. Cases:—Dr. Cotman: Disease of the Ankle.—Dr. F. J. Smith: Osteitis Deformans.—Sir H. Beevor: Congenital Heart Disease. Patients will be shown by Dr. J. H. Sequeira and others.

THURSDAY (28th).—NEUROLOGICAL SOCIETY OF LONDON (11, Chandos-street, W.).—8.30 P.M. Pathological Meeting. Dr. S. Brown and Dr. A. Meyer (communicated by Dr. J. A. Ormerod): Morbid Anatomy in a case of Hereditary Ataxy of the type described by Sanger Brown.—Dr. S. Gee and Dr. H. H. Tooth: A Case of Hæmorrhage in the Region of the Pons Varolii almost entirely on the Right Side.—Dr. W. A. Turner: Symmetrical Softening of the Pyramids and Interolivary Strata.—Dr. F. E. Batten: The Effect of Marchi's Fluid on Nervous Tissue which has undergone Post-mortem Change.—Dr. J. Taylor and Mr. C. A. Ballance: A Case of Tumour of the Right Lateral Lobe of the Cerebellum.—Dr. R. Russell: Contributions to the Study of some of the Tracts in the Spinal Cord.

FRIDAY (29th).—BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11, Chandos-st., Cavendish-sq., W.).—3.15 P.M. Exhibition of Throat and Nose Cases by Dr. Pegler, Mr. Wilkin, the President, and others. Papers:—Dr. Tresilian: Throat Lesions in Enteric Fever.—Dr. Pegler: Post-septal Lymphoma (with microscopical preparations).—The President: Some Lines of Progress in Laryngology, Rhinology, and Otology (Presidential Address): Exhibition of Ear Cases.—Mr. F. Marsh: Notes of Five Cases of Cerebral Abscess due to Ear Disease.—Mr. M. Collier: Nasal Stenosis and Tinnitus.—Mr. W. Wingrave: Tuberculous Disease of Middle Ear complicated by Optic Neuritis.—Mr. St. G. Reid: Traumatic Rupture of Tympanic Membrane.

LECTURES, ADDRESSES, DEMONSTRATIONS, ETC.

MONDAY (25th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. G. Stoker: Chronic Glandular Disease of the Nose and Naso-Pharynx.

TUESDAY (26th).—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Stupor; Katatonia; Dementia and Senile Insanity.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abraham: Alopecia.

HOSPITAL FOR NERVOUS DISEASES (73, Welbeck-street).—4.30 P.M. Dr. H. Campbell: Cases of Hemiplegia.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Ormerod.

WEDNESDAY (27th).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-st., W., 4.30 P.M., Prof. A. Wynter Blyth: House Drainage.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST (Brompton).—4 P.M. Dr. Symes Thompson: Phthisis in Relation to Life Assurance.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—Dr. D. Robinson: Metrorrhagia.

EVELINA HOSPITAL (Southwark-bridge-road, S.E.).—4.30 P.M. Dr. G. Carpenter: On Infant Feeding. (Post-Graduate Course.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq.).—5 P.M. Dr. Morgan Dockrell: Eczema.

THURSDAY (28th).—LONDON POST-GRADUATE COURSE.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. Jonathan Hutchinson: Clinical Lecture.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq.).—5 P.M. Dr. Morgan Dockrell: Tuberculosis of the Skin.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Batten: Muscular Atrophy.

FRIDAY (29th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Anthrax and Malignant Œdema.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

A POINT IN THE WORKING OF THE "INFECTIOUS DISEASES NOTIFICATION ACT."

To the Editors of THE LANCET.

SIRS,—I wish to know if you will kindly inform me whether the port medical officer has any right to interfere with infectious cases attended by the practitioners of the town seven days after the vessel has entered the harbour, the port sanitary inspector having boarded the ship on the day of entry, and all on board declared well.

I am, Sirs, yours faithfully,

Whitehouse, Fowey, Cornwall, Oct. 4th, 1897. W. H. BOGER.

*** If a case of infectious fever was removed from a ship under the directions of a port medical officer, his duties as to notification and as to the patient would cease on such removal. If infectious disease occurred amongst persons who left the vessel seven days after the vessel entered the port, the port medical officer would notify them if met with on board, but not if they were living in the town—unless, indeed, he was attending them in his private capacity.—ED. L.

THE SINS OF THE "PERSONAL" COLUMN.

THE *Kerry Weekly Reporter* for Saturday last contains the following paragraph, and we are invited by a correspondent who sends us the paper to say what we think of it.

> "We are glad to be able to announce that Dr. Fitzmaurice's health is so much improved that we are authorised to state that he intends to resume his practice and will see patients at Cloghers. Dr. Fitzmaurice is also prepared to go to the country to visit cases as usual. Anyone wishing to consult Dr. Fitzmaurice at Cloghers can have a car, free of expense, from Vaughan's Hotel, Nelson-street."

We think very badly of it, but we are not anxious to blame the medical man as he may be the victim of mistaken editorial kindness.

SUGGESTIONS IN SERUM THERAPEUTICS.

To the Editors of THE LANCET.

SIRS,—Much has lately been written about the use of the antitoxic, protective, or curative serums, the sole method of using these serums being, as far as I am aware, by subcutaneous injections. It occurs to me that it might be possible for such serums to be administered with probable benefit in other ways than that of the hypodermic syringe method. Thus, they might be administered by the method of feeding in the same way as thyroid extract or creasote, or they might be applied more locally—that is, at or as near the seat of the microbic attack as possible. In typhoid fever, for example, the anti-typhoid serum could be administered in keratin-coated capsules, and in diseases the result of the streptococcus the anti-streptococcic serum might be tried by the mouth or sterile applications of the serum used locally. Apart from any direct anti-microbic action on the cocci it is reasonable to suppose that some antitoxin will be absorbed as well as toxin. Also in diphtheria, cholera, tetanus, tuberculosis, and pneumonia, the respective antidotal serums, or preparations, might be worth trying in some of the above-mentioned ways. If these serums administered by the mouth were found to act as well as they do when given hypodermically our patients would still be able to hold to their old belief in the "efficacy of a bottle of physic," though probably capsules of the serum for prophylactic or curative purposes would be the favourite method of taking them. One would like first to test, as far as possible, the practical value of these suggestions by experiments on the lower animals. Perhaps some colleagues from this brief letter may be induced to help in arriving at some conclusion as to whether or not these methods are of any use in assisting us in our struggle against the pathogenic bacteria and their toxins.

I am, Sirs, yours faithfully,
LACHLAN GRANT, M.D., C.M.Edin.,
Medical Officer, Gesto Hospital, Isle of Skye, N.B.

Oct. 16th, 1897.

A. B. C.—There is not any regulation of the General Medical Council enforcing the presence of an external examiner at the professional examinations of the Scotch Universities.

A. D. N.—We doubt the inference.

THE MEDICAL KNOWLEDGE OF FRENCH SCHOOLMASTERS.

ACCORDING to *Le Progrès Médical* the following "literary exercise" was recently set by a teacher in a Parisian *Lycée*: "1. A medical officer of La Charité Hospital having need of a human subject in order to carry out some medical experiments makes known his requirement to one of the sick attendants, whereupon the latter promises to let him have No. 46, who, he adds, has only a couple of hours to live. Give the conversation between these two persons in ten lines. 2. Such a speedy arrangement does not suit the medical officer, who is obliged to absent himself for twenty-four hours. Give his soliloquy in five lines. 3. A cordial administered to the afore-mentioned number, while *in extremis*, has so happy an effect that after a long sleep the lately moribund patient awakes convalescent. Give the comic disappointment of the attendant, together with the remarks of No. 46, in a dialogue of twenty lines. 4. The next day the medical officer comes to fetch his subject, but the attendant informs him that the dying man has changed his mind. Give the respective remarks in ten lines."

L.R.C.P.I.—It is not a violation of etiquette. We advise our correspondent to read "Difficulties under the Notification of Diseases Act," which is issued from our office, price 1*s.*

THROWING STONES AT TRAINS.

THE custom of throwing stones at trains is far too common, and in addition to its being almost impossible to arrest the idiots who do such things, the penalty provided by the law is far too light. A peculiarly sad accident arising from this insane habit was reported in the daily press on Oct. 19th as follows:

> "Ben Hitchen, a well-known express driver on the North-Western Railway, lies at Crewe unconscious. He had charge of the Scotch express to Carlisle, and when passing under Hartford-bridge, going at great speed, a stone hurled with much violence from the bridge struck him over the eye inflicting a fearful wound. Erysipelas has set in, and his condition is precarious."

Drivers of express trains are exposed to quite enough dangers from the nature of their ordinary work without having to undergo such risks as the one mentioned above. If the scoundrel who threw the stone is ever caught—though we are much afraid he will not be—he deserves the soundest flogging that a criminal ever had. In a case like this one not only is the driver's life imperilled, but the lives of all those in the train. We sincerely hope that the law may be amended so as to make it legal that any one who either throws any missile at a train, whether he hit it or not, or places an obstacle in the way of a train should be well flogged or birched in addition to a term of imprisonment.

IS TYPHOID FEVER COMMUNICABLE FROM CATS?

To the Editors of THE LANCET.

SIRS,—In sending the enclosed note I would ask if the absence of typical typhoid lesions in a cat's intestines might not be due to some difference in the arrangement of the lymph follicles. Mice have been found to be very susceptible to inoculations of the typhoid bacillus, but I do not know whether they are affected by swallowing it; if they are, then it is easy to see how a cat eating an infected mouse might have a diarrhœa capable of communicating typhoid fever to human beings, even if it caused no "typhoid" lesions in the cat itself.

I am, Sirs, your obedient servant,
A. E. BROSTER, M.R.C.S. Eng.,
Medical Officer of Health, Wirksworth Urban Sanitary District.

Wirksworth, Oct. 9th, 1897.

[ENCLOSURE.]

A brother and sister, aged eighteen and twenty-three years, have recently suffered from typhoid fever, the girl's illness beginning on Aug. 31st, and the boy's on Sept. 2nd. They were together at home between Aug. 3rd and 23rd, the girl for her holidays, the boy daily from his work from night to morning. During that period they went nowhere together, and home was the only place at which they had a common meal. Before Aug. 3rd and after Aug. 23rd the girl was away. The last case of typhoid fever notified in the district was in October, 1896, at the same house, the patient in that instance being the present patients' mother. The house, milk, and water-supply were examined in 1896 and again recently without the source of the illness being discovered. Between Aug. 3rd and 23rd a black kitten, aged about five months, suffered from continual diarrhœa and became very thin. It made most offensive messes about the house, which the girl cleared up. She and her brother were attached to the kitten, and both of them nursed it and cuddled it up to their faces. At the same time there were another brother and sister in the house who have been perfectly well, and both of whom, disliking the kitten, never touched it. After Aug. 23rd the kitten lost its diarrhœa and rapidly improved. When seen on Sept. 10th it appeared to be in good health. On that date it was killed with chloroform and forwarded to the Clinical Research Society, who wrote on the 13th that "as all endeavours to produce typhoid fever on the lower animals have been entirely without result we are pretty certain that our investigation will give negative results before we begin," and asking me to wire if I wished them to proceed. This I did. The report on Sept. 21st was as follows: "We made a careful post-mortem examination of the kitten. The organs and intestines were apparently healthy. There were no signs of hæmorrhages, enlarged spleen or ulcerations. The bacteriological examination showed that the blood and spleen pulp were free from organisms of any description. The cultivations from the fæces both from the small and large intestines contained no organisms which resembled in morphology or cultured reaction the bacilli typhi abdominalis." The history of the cases seems to suggest a possible infection from the kitten and the negative results of the post-mortem examination three weeks after its illness are hardly conclusive that the kitten's illness had no connexion with the outbreak of typhoid fever.

*** Before the suggestion implied in Mr. Broster's communication could be accepted it would be needful to explain the singular fact that in the previous year another inmate of the same house had typhoid fever. Does not this suggest some local sanitary defect which had not been remedied after the first illness, rather than infection through the kitten?—ED. L.

Conjoint.—There is no law in these matters, and our correspondent must be guided by his own private sense of what is right. We think that the affix in question ought always to be followed by the letters showing the university whence the degree is derived.

THE DANGERS OF THE CINEMATOGRAPH.

A CASE was reported in the papers recently of an explosion which happened in connexion with a demonstration of the cinematograph. It occurred in a Wesleyan chapel near Bradford, and the explosion appears to have been due to gas, but after the explosion "a large flame flashed to the ceiling" and instantly there was a great panic amongst the assembled crowd. Several people were injured, but happily the consequences were not worse owing probably to the presence of mind of the exhibitors, who cut off the gas from the apparatus, thus preventing the fire from spreading and avoiding an explosion of the gas in the cylinders. The fact of the large flame flashing to the ceiling leads to the conclusion that the celluloid film of which there are enormous lengths in the cinematograph had fired. We have already commented upon the dangers of celluloid in this no doubt entertaining form of popular show, and in the interest of the public it is imperative that something should be done to reduce the savage inflammability of celluloid. It was stated some time ago that celluloid had been made non-inflammable by impregnating it with certain chemical salts. If this be true some steps should be taken to insist upon the employment of this material in all public exhibitions.

"THE UNQUALIFIED ASSISTANT."

To the Editors of THE LANCET.

SIRS,—As the practitioner who employed the unqualified assistant referred to in your correspondent's (Mr. Tucker's) letter in THE LANCET of Oct. 16th, I think it only fair that all instead of a few of the facts only should be mentioned. In the first place I take every opportunity of showing to any of my patients who may at times be attended by my assistant that the case is under my supervision. In dozens of cases I have told patients that my assistant was not qualified even when they have not asked me. With reference to this particular case Mrs. Tucker showed me so very plainly that she did not want me, and told me that she was more than satisfied with my assistant, that I only saw her as seldom as possible. This is quite contrary to my rule, which is that my assistant shall see any cases as seldom as possible. He does not take 5 per cent. of any visits that come in, and I (not he) would have seen Mrs. Tucker's baby when last seen had she not called in my assistant while he was passing the door. The visit was not sent to the surgery at all. I have never directly or indirectly tried to make people believe that my assistant was qualified. His work consists practically entirely of dispensing and attending simple uncomplicated cases of midwifery. He has never attended any case of midwifery requiring instruments without my presence, when I have always done the operation. I am writing at this great length because I consider the matter a very important one, and also because I want to show that I as well as Mr. Tucker am anxious that people shall not be misled with regard to my assistant's lack of legal qualifications. I am, Sirs, yours faithfully,

Trelyon, Ilford, Oct. 15th, 1897. W. H. BEST.

Sea Side.—It is necessary that the holder of these appointments should be registered. He may or may not possess more than one qualification; this of course depends upon the date of registration.

SCARLET FEVER AND THE PRACTICE OF MIDWIFERY.

MR. BRAXTON HICKS has concluded an inquiry touching the death of the late Mrs. Emily Munday in June last, a week after her confinement. Mrs. Munday had engaged Mr. Whitehead to attend her, but when the time came he was laid up with scarlet fever, in the peeling stage, and his patients were attended by Mr. Bilham and by Mr. Don. Mr. Bilham for the most part attended to the midwifery cases. He lived in Mr. Whitehead's house while doing his work. The patient became ill three or four days after confinement and died in a week. Mr. Bilham seems to have had some doubt about the nature of the disease at first, but with two or three other gentlemen agreed that the case was one of scarlet fever complicated with heart disease of old standing. The husband became anxious to know the source of the infection, and stated that he could find none but Mr. Whitehead. Mr. Felix Kempster, police divisional surgeon, gave evidence. He had made the post-mortem examination, and declared death to be due to old heart disease, probably accelerated by scarlet fever. Asked if as a long-standing medical man he would attend a confinement case while also attending a scarlet fever case, he said, "it is a matter of everyday occurrence." In the end the jury found "unanimously that the death of deceased was due to heart disease, accelerated by scarlet fever, but that how the scarlet fever was contracted there was not sufficient evidence to show. The jury added, however, that they were of opinion that no medical man should attend midwifery cases while he had contagious complaints in hand." The coroner expressed his agreement. The solicitor for the husband expressed himself satisfied with the verdict, and hinted that further proceedings would be taken in another court. Under these circumstances it is well that we should abstain from much comment. Undoubtedly wherever it can be arranged it is desirable that attendance on midwifery and on contagious complaints, especially scarlet fever, should be dissociated; but in this urgent world it is not always possible without greater hardships than such attendance. It is, however, most imperative that the greatest possible care be taken in such circumstances to disinfect the person and to wear clothes that have not been exposed to the poison.

R. D. W.—No. The title of "Dr." implies the possession of a medical degree when assumed by a medical man.

"WARTY NIPPLES."

To the Editors of THE LANCET.

SIRS,—Will you allow me a small space to thank the medical brothers who have written me privately in response to my letter in THE LANCET of Oct. 2nd giving their experience and excellent advice about the treatment of warty nipples in a primipara nearing her accouchement? The condition does not appear to be so uncommon as my own experience had led me to believe.

I am, Sirs, yours truly,

W. J. COLLYER ADAM, M.B. & C.M. Glasg.

Acre-lane, Brixton West, S.W., Oct. 20th, 1897.

THE TREATMENT OF CORNS.

To the Editors of THE LANCET.

SIRS,—I should be grateful if any of my medical brethren could offer me a hint as to the treatment of corns. They are situated on the upper and outer surface of the little toes, are of the usual callous variety, and I think in each case surmount a bursa. For months I have found locomotion a pain and a grief in spite of my best endeavours to obtain relief from the many well-known and published lines of treatment. I have placed the making of my boots in skilful hands, yet I find it impossible to put my feet into them without a shudder. I may add that my general health is fairly good, and for many or most years of my manhood I have been a great pedestrian. Any suggestions will be thankfully received.—Yours very truly,

43, Welbeck-street, W., Oct. 20th, 1897. J. T. JONES.

MEDICAL MEN AS WITNESSES.

AT the Brecon Police-court on Monday, Oct. 18th, a point was raised, as it has been raised frequently before, which is of some interest to the medical profession. A medical practitioner was called by a party to an action. The medical witness said he would decline to give evidence until an order was made that his fee should be paid into court, because his experience in such cases was that the fee was not paid after the evidence had been tendered. The presiding magistrate thought the medical man should take the same risk as other professional men—solicitors, for instance. A solicitor who was present remarked that solicitors took care to get their fees before going into court. The Clerk said a medical man had a perfect right to refuse to give evidence until paid. The Bench decided by a majority not to make an order in the case, and unless the medical man could make an arrangement with the parties who employed him they would have to do without his evidence.

ERRATUM.—An annotation in THE LANCET of Oct. 16th made reference to a paper by Dr. L. Guthrie which had appeared in *Brain*, and quoted the subject of the paper as "Psychro-Anæsthesia." This is a misprint for *Psychro-æsthesia.*

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

TRADE MARK

'Tabloid' BRAND

Blaud Pill

EVIDENCE for or against any medical preparation may be of two kinds—theoretical and clinical. Ingenious theories have been suggested as to the action of many iron preparations, but these are untrustworthy unless confirmed by ample clinical evidence.

A series of 65 clinical trials in a London hospital proved that 'Tabloid' Blaud Pill caused an increase in hæmoglobin of 1·2 per cent. a day, whereas in the case of all other preparations tried it never exceeded 1/2 per cent. Full particulars of these investigations will be forwarded to physicians who desire them.

The *British Medical Journal* reports that 'Tabloid' Blaud Pill "is a certain method of obtaining moist carbonate of iron in a condition very suitable for absorption"; and the *Dublin Medical Journal* says that "the absolutely unoxidised condition of the resultant ferrous carbonate is guaranteed."

BLAUD 'TABLOID' LIST.

Blaud (Pil. Ferrug.) 4 gr. (*plain or sugar-coated*)

Blaud (Pil. Ferrug.) 4 gr., with Arsenious Acid, 1/64 gr.

Blaud (Pil. Ferrug.) 4 gr., with Aloin, 1/20 gr.

Bottles of 25 and 100, 6d. and 10d. per bottle.

Blaud Pill, 5 gr., with Strychnine and Arsenious Acid, 1/100 gr. each.

Blaud (Pil. Ferrug.) Compound.

℞ Pil. Ferrugin. ... gr. 5
Pulv. Capsici ... gr. 1/4
Aloin,
Strychninæ,
Acid. Arseniosi, *aa* gr. 1/30

Bottles of 100, 1s. 8d. per bottle.

The above are supplied sugar-coated only, unless otherwise marked.

Specimens and clinical reports forwarded on request.

"A perfect combination of Malt Extract and Cod-liver Oil."—*British Medical Journal.*

BYNOL

The "PERFECTED" Malt and Oil.

BYNOL, though containing a much larger percentage of COD-LIVER OIL than the ordinary preparations of MALT and OIL so widely sold, is, nevertheless, not only free from all unpleasant taste, but has a most agreeable nutty flavour, so that it is relished as a sweetmeat by many children. It can be taken without difficulty by delicate patients, being readily digested and assimilated. This result is due in large measure to the intimate combination of the MALT EXTRACT with the OIL, globules of the latter not being distinguishable even under a microscope.

The Malt Extract employed is exceptionally nutritious and active, while the Cod-liver Oil is of absolute purity, being made at Allen & Hanburys' own factories in Norway, from the fresh and selected livers of the Cod-fish only. *SAMPLES FREE TO MEDICAL MEN.*

The late Sir ANDREW CLARK, in a lecture at the London Hospital, remarked:—

"I have said that these fibroid cases are poor creatures, thin and white, and have what may be called nutritive debility, and the question is, What am I to do with them? You cannot do better than endeavour to make the patient walk in the way of physiological righteousness. But that sometimes will not do. Some people may be physiologically well behaved, and somehow they do not thrive on it. Can you do anything in those cases? There are two remedies which sometimes do succeed where the ordinary diet will not succeed in nourishing the patient—the one is Cod-liver Oil and Malt given with food—a preparation called BYNOL—*and the other is the remedy called* BYNIN EMULSION, *consisting of Hypophosphites, Oil, and Malt; both are prepared by Messrs. ALLEN & HANBURYS. These are two good nutritive agents in promoting nutrition."*

ALLEN & [illegible] LTD, P[illegible]

An Inaugural Address

ON

MAN AND MEDICINE.

Delivered at the Opening of the Session of the York Medical Society on Oct. 13th, 1897,

BY J. F. GOODHART, M.D. ABERD., F.R.C.P. LOND.,

PHYSICIAN TO GUY'S HOSPITAL; CONSULTING PHYSICIAN TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—I understand that I am to address this afternoon more or less of a mixed audience, and I long ago made up my mind that if ever such an opportunity presented itself to me, although in doing so I should have to say again many things that at other times and in other places I have said before, I should address myself in the main to the lay element amongst my hearers. Some alleged remedy has conquered pain for fifty years men read as they walk the streets, and many a one believes it—or at least the principle it embodies, and this or that nostrum is bought in consequence, and thus advertisements pay. The man of medicine, on the other hand, turns aside and smiles at the advertiser on the one hand for his brazen impudence, and at the man in the street on the other because he is such a simpleton. It is evident, therefore, that the natural man and the regenerate, if so I may venture to designate the layman and the medical man, look at things from very different standpoints, and it is this difference that I propose in some fragmentary way to consider to-day.

Now when a man is sick he wants to get well. Why does he want to get well? Why ask such a question? you will say. For several reasons that are all too plain. He may have his business to carry on, which no one can do as well as he; there are the care and support of those who are dear to him; there is the discomfort of being out of health, &c. And yet I doubt, important as they are, if these are the most potent elements in the desire for health. For the moneyed man—even more than the bread-winner who *may* sometimes get temporarily tired of life when fagged by the burden and heat of the day—even the wealthy man, I repeat, is just as keen on getting well. Now some would say that this is due to the discomfort, too often distress or pain, of the sickness. Others might hold that the presence of sickness was the shadow of death. And I do not doubt that these things do enter in some measure into the result; but the wish to get well is, I believe, conditioned and inspired by a more active influence than these, and is nothing less than an intense unconscious necessity of living that is implanted in each living thing as it launches into being. "I have often sat to enjoy the view on the side of a hill in the neighbourhood of one of the towns of the Riviera, where far down at the bottom of the valley is a small public abattoir, and I have repeatedly noticed that animals, both singly and in flocks, have wended their way to their doom in perfect peace of mind until the very gates of the charnel house were reached. Then suddenly the scene changed and all was commotion: the animals duck and tumble, run here and there, and do all they can to avoid an entrance into the fatal enclosure. Who can doubt that a sure intuition of danger has been stirred and that unreasoning reason points them clear? Who has not noticed how instinctively a horse will recognise the near proximity of a corpse of its own order, and how it will snort and plunge to get away from the noxious thing? It can hardly be supposed that the lower animals have any *experience*, and therefore fear, of death. They must scent or sight a something that—like the sight of a little blood to many a strong man—makes the heart faint. This living principle, this nervous current, this anima, this soul starts us on the road of life and keeps us going, and the first breath of the sense of its failure produces the foretaste of death. Ah, these foretastes of death! They come to some apparently, and very terrible they are. I remember once watching by the bedside of a strong man in the pride of life who had had a sudden hæmorrhage. So far as I could see there was every hope that the danger had passed; yet there remained a restlessness and an anxiety about the patient that I could not explain. But I knew in a few short hours that he had recognised in some unconscious way what I could not, that in his pulsatile existence some link had gone and had brought him the presentiment of dissolution. The silver cord was loosening and produced a sensation that rightly forecast the issue. This is a somewhat unusual case, but there is a larger number of instances where, I believe, a like sensation comes, and although these people never die they appear to suffer an appalling sense of impending annihilation. Many a woman—aye, and strong man also—has described, or attempted to, this indescribable feeling, a sudden, fearful collapse that seems almost to give them a look over the precipice into the next world, and then leaves them, laughing, as it were, at the poor, helpless, terror-stricken things, with every fibre trembling as from a fearful nightmare.

We are often inclined to smile at what, perhaps, we think the overdrawn picture that the subjects of this complaint portray—to say, or think rather, "Oh! a nervous man or woman," and to pay little attention to their plaints. But I suspect that the suffering that these people undergo is a very real one and that it merits our best attention and sympathy. Happily, the infliction does not come to many. I am never tired of saying, because I am sure it is as true as it is comforting, although in opposition to the general belief, that death has no terrors for the sick man. To the living and healthy man it is quite otherwise, but the sick man upon whom death lays his hand pales gently and imperceptibly out of life. The unwitting legacy of sorrow, sadness, and distress is left around and behind.

At the bottom of all such episodes as I have mentioned there may be, if you like so to express it, a terror of death; but if it be so it surely never comes to the individual in any concrete thought as such. There is rather some sudden shock that is born of interference with an intense well-spring of being; with—oh, well described—the breath of life—a condition that one can best conceive of perhaps by supposing that our driving power, of which I am going to speak again presently, suddenly gives a jolt, or momentarily fails, like the electric light does sometimes, and then goes on again, and of which we can conceive as a by no means pleasant experience. It is said of someone that upon remarking that he must live a companion responded that he did not see the necessity. But that a man must live is a great truth for the individual. Living is an imperious necessity of unconscious energy that we cannot away with, and it is this that seems to make of suicide so unnatural and morbid an impulse. I am no believer in *felo de se*. It may possibly seem to some that this is labouring a point that has not much in it. But it is not so. For if I say that every man is possessed of an intense love of life it will at once be said that there are frequent exceptions. Many a man says, no doubt, that he or she does not value life for its own sake, and there are those who regard a love of life for itself as a selfish or cowardly feeling. Therefore I think it is important to contend that, whatever the living principle may be, it is involuntary, irrepressible, and intense, that it compels to actions oftentimes against our wills, and it is this fundamental living momentum that plays a large part in inspiring the somewhat peculiar attitude in which man stands to medicine—an attitude that in many ways is still even at this the end of the nineteenth century oftentimes quite irrational. For instance, take first the diagnosis of disease—that is to say, the finding out what is the matter with a man. There are few indeed of the sick or of his relatives who will allow that there can be any doubt as to the meaning of the symptoms. That is to say, although when the medical man is in doubt they will admit it is impossible to tell at once what is the nature of the complaint that is setting in, they nevertheless act as if no doubt were allowable, and it speedily is made evident to the medical man that to doubt counts against the doubter for incompetence, and some other opinion is sought to settle the matter. But what are the facts? The boot is so much on the other leg that I would rather contend as the more nearly true that there are few cases if our thoughts were laid absolutely bare that are entirely free from all element of doubt. Every walk in life is paved with uncertainty. Is it likely that the problems of medicine afford easier solution? On the contrary, it is certain that, resulting as they too often do from conditions that we are quite unable to measure in any way, they are too often incapable of solution in any dogmatic way. Only

yesterday a young man came to me for an opinion. I found as he unfolded his tale that he had seen all the men of the best repute in London. The case presented two alternatives. About half had taken the one view and half the other. He had not paid me the compliment of taking my casting vote, but took me by the way to yet other opinions. I therefore put it to him what was the common-sense explanation of the difference of opinion that he had obtained. There could be only one, and it obviously was that the question he wanted solved was insolvable, and that all he had to do was to accept the situation. But I know he will not. I am afraid it is not in nature to sit down in doubt in the matter of one's health. But doubt must be. You see the symptoms of disease are pain and fever and alteration of the appearance and shape of parts, and so on. And pain, alas, is common to many diseases. Fever also is common, and the enlargement of an organ may arise from several different changes of structure, and still more numerous diseases according to the combinations that come of the re-arrangement of the several morbid changes. No wonder then that the diagnosis of disease is at times at fault. And it were better always to bear in mind that "knowledge brings doubts and exceptions and limitations that are all hindrances to vigorous statement." Yes, it is experience that raises doubts. I am sure that hardly a week passes by in which I am not asked to decide upon the nature of a doubtful case of fever—chiefly whether it be typhoid fever or not. And it is often, indeed, that I am unable to do so. Quite different diseases may have certain features in common, when it is impossible with our present knowledge always to distinguish one from the other. Such a group is formed by influenza, typhoid fever, septic endocarditis, and a form of what the public call "galloping consumption." One often has to wait in such cases until the negative has gradually developed. And because the public will not wait all sorts of things are lumped into the group of typhoid fever that are not of that nature at all.

Take another case. You go to a specialist to ascertain whether you have early phthisis or not, and because you will not take "I am not sure"—you must have a positive opinion—the investigator's judgment is biased, and over and over again a man has been said to have delicate lungs when there was nothing at all the matter with them. It may, of course, be the other way, and that a patient is let off when he ought to have been condemned; but this is less common than the other because it is safer to tell a man that he is delicate and must take care of himself than to say that he is sound and thus lose the opportunity of betterment which an early diagnosis affords and risk a subsequent breakdown. It is impossible to be sure in many a case of early phthisis but the public cannot understand the difficulty, so there is many and many a one roaming about the world condemned to a useless existence because in such a question years ago innocent or guilty were the only verdicts recorded. I grant the importance of a positive opinion when it can be arrived at. But I object to being driven into giving a decided opinion when there are really no sufficient grounds for arriving at any conclusion or as an alternative of being considered incompetent. What's in a name? Well, a very great deal to the general public. I am constantly told: "You must give the disease a name." As soon as the average man has his disease ticketed he seems to be quite happy. He thinks then that the medical man knows all about it. If his disease cannot be ticketed he assumes that the medical man knows nothing about it. Some years ago I saw a woman who was obviously very ill with chronic diarrhœa. It was possible that the real nature of the disease was of cancerous character, but acting upon a rule I have long made for myself, that of two opinions, if the one is hopeless choose the hopeful one if you honestly can, I told the family that the malady was a chronic diarrhœa. Some few weeks later I received a letter from the son to say that having taken so much interest in the case they thought I should like to know that their dear mother had died from sprue. They seemed to be quite content that their dear mother should die from sprue, which is chronic diarrhœa, but they were not content with anything so very commonplace as the synonym that I had applied to the complaint. That did not seem to them to be a disease.

Again, it often happens that someone suffers from a doubtful tumour. It may be a cancer, maybe not. The opinion of the man who is not sure is worth nothing. The patient is therefore taken by his friends from one medical man to another till a decided opinion is obtained. And I have often noticed that contentment is arrived at even with an adverse verdict, provided that there is no longer any room for doubt as to the nature of the malady. But this seems to me to be a most irrational proceeding, for where the satisfaction comes in it is hard to see. And this leads me to say, though it is a little beside the mark, that this is not done by the sick man in most cases. He always clings to the man who will give a hopeful outlook. He may sometimes tell you that he wants to know the truth, but in the greater number of cases he is really hoping to hear that the outlook is a favourable one, and I have several times known, when, in response to an entreaty, it has been revealed to the sick man that his prospects of health were bad, that he has shifted his patronage to some other medical man who can take some more mitigated view. The sick man cannot go outside himself, and that living principle of which I have already spoken will not let him give up hope; and in respect of this point I am often told that this one or that one "will want to know everything. What are you going to tell him?" I reply: "I shall answer his questions"; and I seldom find that I cannot do so, because it is seldom indeed that anyone asks me that tremendous question, "Am I going to die?" Man is incapable of looking at the worst. This is not because he has no hopes for the future, it is not that he is determinedly blind—he simply cannot do it. I have seen some striking instances of this. I remember a medical man who suffered from a disease that if he had seen it in one of his patients he would have said, without a shadow of doubt in his mind, "This will end his life before long." But in his own case he never, so far as I could see, looked that way at all. He made all his plans, on the contrary, as if he were going to get well, and, as I firmly believe, he hastened his end by the extreme rigidity with which he applied himself to getting well. I accept, therefore, this as a great fact in human life, I take it that a kind providence has ordained it so, and I decline to interfere, as some would seem to wish me to do, and spoil this beneficent attribute of life. If a man has a malady that may be, say, a cancer, maybe not, I say, if it be a cancer there is an end of the matter; nothing more can be done save to alleviate symptoms. You had much better hope on and do the best that that hope affords. You are none the worse off, and you are free for a time, speaking only from the human point of view, from the complete paralysis of despair.

And while upon the importance attached by the public to names perhaps I may say also how very careful a medical man has to be in the use of his words. Indeed, for this reason the older one grows the less communicative a man becomes. For instance, it is not at all uncommon for things to fall out thus. You go and see a case of pleurisy, thus rightly called by the medical man of first instance; and in discussing the matter with the friends you in natural course talk of inflammation. Quite speedily the scene changes. They exclaim at once, "Oh, he has got inflammation, has he? Doctor A. never told us that." To have got the inflammation is to be all right or all wrong, as the case may be. The term either satisfies or alarms. On the one hand, it is one of the diseases that the layman *recognises*, and therefore he knows where he is, and meeting with an old enemy he proceeds to subdue it by turpentine, mustard poultices, various embrocations, in many cases the medical man standing afar off. There is no obscurity about "inflammation"—anybody can treat it—and in this light it is a term of satisfaction. On the other hand, with some inflammation is a word of terror, a thing which, if you do not quickly get the upper hand of, will quickly have the upper hand of you; and so if you have, say, a pleurisy, and have not thought of it hitherto, or heard it talked of under that head, you are very likely to think that some new discovery has been made in the nature of your complaint, and that there has been some serious oversight.

Time would fail me even if I could remember the many curious twists and contortions that the original meanings of words undergo when, having been stated plainly, as he thinks, the medical man hears them translated again by others. "The doctor says I've got slugs in my liver," says an old woman. "No," says her listener, "he didn't say that; he said you had a sluggish liver." "Yes," replies the old woman, "they be the very words he used." And there is another side to this matter, for the public are curiously *gauche* sometimes in their use of words. A medical man wrote thus to me the other day in sending a case for an opinion. "I would," says he, "have commended him to you as being a particularly decent fellow had he not remarked to me

Digitized by Google

when I suggested the consultation that he thought he would like some *good* advice." Well, then, those doubts that I have spoken of lead me to another difficulty between medical men and patient. Any excessive caution, as it seems, on the part of the medical man is often keenly resented by the patient. Say, for instance, that a young woman consults me for acute indigestion. She has suffered years before from hæmorrhage from a gastric ulcer. She was then treated quite properly by a man who knew his business by rest in bed and a somewhat long attendance, and now, fearing a repetition of this, she comes to me hoping to avoid it. She is quite angry at being sent back again after all to bed and her old friend, and thinks it all nonsense, if not worse, a job. And I am not altogether without some excuses for her. She is very human. I know that when I take my watch to the watchmaker because it has somehow perversely ceased to go he always seems to me to say, "Yes, sir, it has had a fall and the cylinder is broken." And I, knowing nothing about watches or how small a jar may disturb and disarrange their constitution, disallow the reputed blow, and have a strong doubt about the correctness of the watchmaker's diagnosis of a damaged cylinder, more especially because it seems to be about the most expensive breakage that can happen to a watch. Now, the public seems to me to regard medical men from the same point of view that I look at my watchmaker. They know nothing about medicine or the reasons upon which such and such advice is based. They only know that the recommendations are disagreeable, and they think, therefore, in much the same strain as is here recorded in Mr. Gilfil's love story: "Dame Fripp kept leeches and was understood to have such a remarkable influence over those wilful animals in inducing them to bite under the most unpromising circumstances that though her own leeches were usually rejected from a suspicion that they had lost their appetite, she herself was constantly called in to apply the more lively individuals furnished from Mr. Pilgrim's surgery when, as was very often the case, one of that clever man's paying patients was attacked with inflammation."

Another point that the man in the street does not seem to be able to grasp in the least is that all our organs are interdependent upon the integrity of the whole. It is impossible that he can do so when the rage for specialists is so severe. A man treats his component parts as separate entities, and physics this one or that according as it shows signs of what he considers as defect. But the curious part of it all is that although he is very ready to believe all manner of ills of his liver, his heart, or kidney, or what not, he never seems to think any evil of his brain. The only brain disease the public knows is insanity. It is very keen in its dread of going out of its mind, and many a man, I believe, does so from very fright and brooding on such a terrible possibility. But as to the brain having any connexion with, much less control of, say, the stomach or the liver or any other part, they have no conception. Now, I do hope that I am not running away with an idea; but if not, the great proportion of people that come before me are suffering, not from disease of this organ or that of the digestive or circulatory system, but from deficient driving power in their nervous centres. Their brain cells and nervous centres want stoking to enable them to distribute their energy better; to enable them to exercise more effective control over the action of the viscera to coördinate the action of this one and that one, and, perhaps best of all, to learn to control themselves. Their worst enemies are often they of their own household. These people, as a rule, want very little medicine, they have usually taken already more than enough; but what they especially require is a talk upon elementary physiology; it is only thus that any adequate explanation of their various ills can be given them, only thus can they be made to understand why they are sound yet out of health. Did these people but know a little more about themselves how much more healthy and happy they would be. It was but recently that I was advising a man whose heart had failed for the second time under the effects of prolonged mental work. One of the most intelligent of men, he had nevertheless often maintained that brain work has no influence on the body. This is only another way of stating that old absurdity that it is worry, not work, that kills. If all you mean by work is that healthy physiological exercise of a part does not wear it out the aphorism is self-evident and meaningless. If you mean that work that eats into the time that is required for rest and recuperation, whether by sleep or holiday, does not kill, then it is absurd. Do you suppose that a man can go buried in, say, financial problems for many hours during the day, leaving him no time for exercise and little for sleep, without suffering from short commons of nervous energy in other parts of his economy? Therefore, continuous work of any kind—over-work—that trenches upon the necessary physiological rest will kill, or produce functional and organic disease of one kind or another. And I have not a shadow of doubt that one man may come to you always tired, another with a palpitating or a dilated heart, another with indigestion, another with some other organ at fault, because the central nervous system, that ought to energise the whole, has played itself out incontinently on its own account, and the reserves for the local centres are exhausted. Let us next take the question of drugs, because it well illustrates the difficulty there is in treating adequately the subject I have chosen. It is so bound up with the contrariety of attitude exhibited by the public. For a good large section of mankind in the civilised world the love of physic, or perhaps I ought rather to say the craving desire to swallow it, appears to be unconquerable. Do you question it? Then go into the first druggist's shop as you leave this room and stand in its centre and ponder. It is true the proprietor may think you a lunatic, but you ought to learn a useful lesson at this small cost. A druggist's counter always seems to me an appalling thing, until I fall almost to questioning the advantages of a civilisation that has brought us to such a pass. I have always contended that as the world grows older it tends to grow more nervous. I do not see how it can well be otherwise if you and I are at one in what we mean by nervous. I do not mean timid, I do not mean mad. Either of these imputations, which he often supplies for himself, the man in the street is highly resentful of. I mean that as the world grows it is brain that is pitted against brain, and ever and ever increasingly so. It is not liver against liver, or kidney against kidney, or heart against heart, or only indirectly so. The strain does not come on the individual workman, but on the foreman of the works who has to regulate and coördinate the whole. Thus it is nerve that is pitted against nerve until the brain becomes more intricate, a more and more perfect mechanism, and in its perfection all the more readily likely to break down or get out of order. I do not see what else is possible. I am told that in the days long gone by, when living and life were very insecure, there was much more to upset one's nerves than there is now. I do not see any force in that argument. In those days it was more directly heart against heart and liver against liver; the strongest animal lived the longest. In those days strength of body counted for everything. But now the scene has shifted, strength of body occupies a subordinate place, and the rude rough life that made one tough, except in so far that a reasonable cultivation of a strong body is necessary to a sound nervous system, has given place to what sooner or later was bound to be, the commanding influence of the brain. I am told that the brain of the ancient was as good as ours. But again I think that the argument is faulty. For I take it that the history of states is like the history of individuals, that for both there is a birth, a period of growth, a zenith, a decline and fall. Of all the great states of old, where are they now? and it is to me one of the most interesting questions of the day whether it be possible in our attempts to bolster up modern Greece to re-endow a nation with a second life. For myself, then, I do not doubt, though it may be as yet a far cry, that England must decay. It will live again, but not as England; it will be, as we live, in our children, in the nations that are now growing up, as the American nation, the Australian nation, the Canadian Dominion, and so on. Civilisation leads inevitably, apparently, to luxury, and the luxury of life tends to degeneration, and so a nation gradually becomes effete and dies. And in its period of gradual decay it sees its children taking on the spirit of its glory in new lands, where, again, life is less secure; where, again, man has to obtain his bare subsistence by the rude instincts of self-preservation; and where in a more animal existence he is kept more physically robust. It may seem a sad thing to hold that progress and development bring on decay, but so I think things are at present. But we may well hope that at some time or other in the world's history some community will emerge that shall have solved the great question how to live. To live such a life of physiological righteousness individually and collectively that no one organ or sense or function will be cultivated to the detriment of the rest, and that excess of luxury which after all can only be a parasite and in no sense a necessity of progress,

Digitized by Google

may thus be curbed, and all the higher intellectual faculties left free to act towards a progressive individual and common good. But the history of societies teaches I am afraid that this is no condition easy of production. One might even fear it were impossible. At any rate, the individual feels, and feels acutely, if he thinks at all, that so great is the resolution constantly required to attain an end of this kind that most of us might well apply to ourselves the *positive* of St. Paul's conditional and say, "When I have preached to others I myself shall be a castaway."

Now I think the latter-day increase of the number of drugs applies itself to my argument and enforces it. You cannot suppose that if one of our best furnished druggist's shops were straightway planted, say, in Central Africa that there would be any use for the greater proportion of its constituents. I daresay the blue and green and yellow and red of the windows might secure the adoration of the natives, in fear lest the end of the world had come, and which the instinct of life, there as here, would resent. The interior might even strengthen the intensity of their religious beliefs, if they should light upon some of the more potent remedies that made them "see stars." The medical man who knew his business would probably select, say, some fifteen common and valuable remedies which, unlike Sir John Lubbock's 100 best books, I will not name, lest you should exclaim as I did, "What a poor dull lot!" and of all that large remainder I fear it would have to be said, not only that they were not wanted, but that they spelt absolute harm to the poor savage. Now mark, I do not say they therefore mean harm to us, but they do mean, they must mean, since they multiply daily by leaps and bounds, that we have in our civilised state numberless ills that rude nature is unfamiliar with, and, also, I surely believe that we appeal far too readily to potions and pills for ills that are little *worries* rather than ills. In other words, our nervous centres take much more ready cognisance of ills than robust organisms should do, and we thus use many drugs to live still more the life of luxurious ease. Yes, we most of us take medicines too readily; but there is one thing that few of us take, and that is advice. I sometimes see as I go along the streets a notice in certain windows—not devoted to the emissaries of the law—"Advice gratis." And I always count medicine an unhappy profession because we all know that if that notice read "Advice charged for" not a soul would go near that druggist's door. The law is much better off because it charges and is paid for advice that is also not taken, unless, indeed, it be as medicine under compulsion in the courts with the nose pinched. But neither is that legal betterment the day towards which my hopes go forth for medicine. I look for the day when the world shall pay adequately for and take advice, and physic—well, yes, physic certainly, but only if we medical men deem it necessary. But that is not the idea of the present. Perhaps you think it is. Oh, dear, no! I have a vivid recollection of talking for an hour to a poor fellow, and I remember that I was stirred by a considerable emotion because I thought that I had saved my friend—by *advice*. Judge, then, of my feelings when I heard afterwards that all the time that he had been listening so attentively, and, as I thought, so receptively, to my advice he had got the name of some other man upon his shirtcuff and that he went at once to him and got a prescription, and, unsatisfied by all my talk, a bottle of medicine had put him at rest. Then I have a dear friend in the commercial world who believes in me. It flatters one a little to be believed in by a hard-headed son of the City. But he always tells me, "If you don't cure me in three visits I shall go to someone else," and ever and anon he comes gently ruffled into my room with "My dear fellow, So-and-So has been to you and you never gave him any medicine." "No," say I, "he did not want medicine." "That doesn't matter," responds he; "he came for a prescription and he ought to have it People don't think anything of you if you do not give them some physic." And that is all true. My friend quite rightly describes the attitude of the public. It thinks that medical men know much more than we do. That there is a remedy for every disease, ay, every symptom, if only the medical man be clever enough to find it. So if they do not get well "in three visits" they go to someone else. But that is not the way we who know look at things; we see too many diseases that can only be watched, for which there are no present indications for giving drugs, and for, I suppose, the large majority of the ailments that flesh is heir to time is at least as important an element in the cure as any drug. There are others that rest only can cure. Time after time people come to me with an ailment for which they have been taking medicine for weeks, but they had not taken the most important curative agency, rest in bed or a holiday. People will swallow any quantity of nasty medicine, but go to bed, oh, no! that is *weakening*. They will swallow any number of pills to keep their livers up to the mark, but stop their whisky or their daily port, oh, no! they know much more than the doctor about that, and, indeed, "Dr. So-and-So said years ago that I wanted keeping up." Keeping up lays many a one low. Only recently have I seen a man who has tabulated out all the years of his sexagenarian life, and the illnesses he has had in each of many years of it, and the many medical men he has consulted. I am his latest hope. I am afraid it is a case of

"Late! late! so late! you cannot cure him now."

But he is still in full and keen pursuit of health as he has been these last thirty years. He still believes the El Dorado of his health is somewhere near, and yet I was obliged to tell him that the nugget of which he was in search had been long ago buried within him, bound round with grave clothes under the garb of prescriptions.

Medicine can hardly progress to its full expansion so long as this present overblind faith in a nostrum prevails. The uncertainties in all directions are so great that the man of knowledge and experience with all his correct appreciation of the essential details of the case, and therefore generally correct diagnosis, with all his plumbing to its depths the most recent advances in applied therapeutics, may yet miss the mark, and the ignorant man or the quack coming in at the end may fire the last shot and appear to take the fortress and thus run off with the prize of an unearned credit. The public judges entirely by results—I confess I do not see how it can do otherwise—and yet as a criterion the result of a case is repeatedly faulty, for it too often brings reputation to the quack while the honest and wise man is sent about his business in more or less of quite unjust and undiscerning discredit.

But there is a class of people who will take advice, but who run to the other extreme. Here also may be traced a too exaggerated opinion of the medical man's knowledge. We are asked, for instance, to tell a given person what he may eat and drink, and perhaps some one may think: "Well, what more natural or sensible?" Well, natural I admit it is, since so many ask it. But sensible, I am not so sure about. Think it out for yourselves, each one for himself, and you will, I think, find much wisdom in the adage: "A man is either a fool or a physician at forty." Before forty you are not worth much if you cannot eat anything (I do not say drink), and by forty you ought to have arrived at certain conclusions as regards your own individual working that are far and away more trustworthy than any a medical man who does not know you can offer you. I do not for one moment underrate the value of the advice that a medical man who does know you can give you. What I want to drive home is that the exaggerated belief in the precise regulation of all the minute details of your daily life does not lead to your applying to him for advice. A trusty general practitioner who knows you, who has probably watched your growth and life for many years, who knows your quips and cranks of constitution, he can think these matters out with some bases to go upon, and undoubtedly he can help many a man to help himself. He cannot do more—mark that; he can only help a man in most cases to help himself. But this desire for the detailed regulation of your life leads you in nine cases out of ten to a specialist who is supposed to be skilled in diet, and that is nearly always to a so-called fashionable physician or, worse still, to an arrant quack. But what can a stranger really know of you and of your constitution in twenty minutes or half-an-hour's talk? If he be a wise man you will probably come to no harm because his wisdom will keep you on the lines of common-sense. If he be a faddy man you consign yourself to a fad, and thus a large proportion of mankind at one time is drinking hot water by the pint; at another drinking no water at all—at least, not at meals; and at another it is rushing off to some latest fashion in watering-places to cure itself of a disease it has not got, or of a disease, perhaps, for which there is no cure.

And this leads me on to the question of specialists. The public will have specialists. Now, it is admitted at once that for parts that are subject to local diseases and that require delicate surgical treatment a specialist is absolutely necessary. The steady hand and eye of an enormous operative experience is necessary to ensure the best results, but as

Digitized by Google

regards specialism in medicine it is a rank absurdity. Who is the best man for the heart? Who for the liver? Who for the kidney? Who for the brain? Who is the specialist now on gout, who on asthma, who on this and that are the questions asked on every hand. The man in the street is very fond of talking about his constitution, and yet he is ever doing despite to his very sensible idea when he runs off to a specialist for his liver. He goes off, as he often says, to the fountain head. But in doing so that constitution is clean forgotten. There is that personal element in all diseases that makes medicine still so much an art, and too often in going to a stranger the key to the lock has been left at home in the charge of the family practitioner. "'His father was here afore him,' Mrs. Macfadyen used to explain; 'atween them theyve hed the countyside for weel on tae a century; if Maclure disna understand oor constitution wha does a wud like tae ask?' For Drumtochty had its own constitution and a special throat disease as became a parish which was quite self-contained between the woods and the hills, and not dependant on the lowlands, either for its diseases or its doctor." And having mentioned the constitution and the general practitioner as being *facile princeps* in all questions relating to it, I may say a word upon a cognate matter which perhaps may be called an ethical one except that I dislike the term. All our ethics is comprised in that very old and tersely expressed formula, "Love your neighbour as yourself." I allude to the relations between medical men and their patients. I believe, as a matter of fact, that when you consult a lawyer the official record of the transactions—in other words, the deeds—are kept by him; they are put into a black tin box with your own name in gilt outside, and thenceforth you and your lawyer are one. At least, that is my case. I should need, being nearly a teetotaller, at least three stiff glasses of brandy to enable me to sever my connexion with my lawyer, and I am by no means certain that that would do more than change, so to speak, the character of the bond that united us. But in medicine it is very different. Between the medical man and his patient the only bond of union that is at all of a material kind is that the medical man dispenses the medicine. And the patient, though he will sniff and sniff again at the bottle to try to detect the ingredients, and very likely ask a friend with a reputedly more educated nose to sniff too, is practically helpless in the divination required and is unable to tell what he is taking. But, unfortunately, this is too often a bond of discord, not of union. The average Englishman does not like being under the thumb of anyone, and when he does not know what medicine he is taking he considers himself under the thumb of his medical man, and he by-and-by slips off to some neighbouring town to get, as he *says*, "an unbiased opinion," and with it, as he *thinks*, a prescription, that he may be a free man once more and know what he is taking, and pass his good fortune, maybe, on to someone else who happens to be suffering from very similar symptoms, but from an entirely different disease. And if there be anything that shrivels up a medical man's bowels of compassion it is an action such as this. It must be so; for an old friend of mine, a medical man, in reply to a kindly note I had written to him on the birth of his firstborn wrote back in this curiously Malaprop fashion as one of the chief elements of the happiness of his situation: "Thank God! I am out of the range of the curse of consultants."

Patients and medical men look upon their mutual relationship from different points of view. The man in the street in this instance takes a business view of his association with his adviser. He considers that the payment of the bill is the just equivalent, the *quid pro quo* that settles all claims—indeed, he has been known to think that the *quid* was more than the *quo* and to grumble thereat—and that he can henceforth try, if he be so minded, the latest fashion—the young man who has just come to town, and who is "so clever" (it is only the young that are "so clever"). But the medical man looks at things very differently. He feels, and rightly feels, if it be kept within due limits—but I think we are inclined to push it too far—that in the great majority of cases he undertakes responsibilities, undergoes sacrifices, and enters into delicate relationships by becoming in large measure a partner in other people's anxieties and sorrows as well as having to bear all his own, for the wear and tear of which no money payment is an equivalent. The only payment that we accept as payment *in full* is gratitude, and gratitude for imponderable service such as medicine renders to mankind is too often a stream with full head which rapidly gushes itself out. There is much truth as well as humour in "Gratitude is a lively expectation of favours to come." No medical man could be such and conduct his business on purely business principles. I will not claim for the profession of medicine that it is more righteous than any other calling in life, but I should always maintain that, however much the public might think and wish to have it otherwise, the larger half of the practice of medicine is, and must be, pure philanthropy. Not a case comes before one probably but that much more is done for it than ever the patient supposes. He supposes that he comes for an opinion and he gets it, and that that is the whole of the transaction. If that were all one had to do medicine would be much simpler, perhaps, but it would be much less enthralling. But before forming an opinion you probably have to throw yourself into the position in life of the patient as far as possible, to realise yourself his hopes and his fears, his troubles here and his ties there, and numberless things that have nothing to do with the disease, but everything to do with the treatment and with your power to give the very best advice that the circumstances of the case admit of. And when you have come to an opinion there is then again the necessity of entering into the man's feelings and shaping your words in accordance therewith. Thus at the end of any investigation the larger number of items in the bill cannot possibly be discharged by any equivalent in gold. You have been obliged, even though willingly, to become the friend and confidant of a family, and friendship and sympathy cannot be bought or sold. It is often said, "You doctors are hard men." I have even heard it said of the ladies who have taken to the practice of physic that they, too, upon occasion are not too conspicuous for the exhibition of sympathy. Well, a medical man cannot wear his heart upon his sleeve. I sometimes reply if you could but join us you would know that it is scarcely possible to be hard in the practice of medicine. The outsider knows nothing of the storms of anxiety, born entirely of sympathy, that sweep through the mind of the medical man when harassed by a critical case. Have I done the best possible thing? is present night and day, perhaps for many days together, upon such occasions, and the relief that is experienced when the sick one emerges from danger is so keen that it can only be compared to the feelings of the convalescent himself when he returns to the pleasure of living.

"'Can naethin' be dune, doctor? Ye savit Flora Cammil and young Burnbrae, an' yon shepherd's wife Dunleith wy, an' we were a' sae prood o' ye, an' pleased tae think that ye hed keepit deith frae anither hame. Can ye no think o' *somethin'* tae help Annie, and gie her back tae her man and bairnies?' and Tammas *searched* the doctor's face in the cold weird light.

"'There's nae pooer in heaven or airth like luve,' Marget said to me afterwards. ..... 'Oor herts were as water afore Tammas's words, an' a' saw the doctor shake in his saddle. A' never kent till that meenut hoo he had a share in a' body's grief, an' carried the heaviest wecht o' a' the Glen. A' peetied him wi' Tammas looking at him sae wistfully, as if he had the keys o' life an' deith in his hands.'"

Thus there does grow up in the medical man's being a sense of a peculiarly close interest in the life that in God's good providence he has helped to steer through the quicksands of illness, and he comes to look upon his patients as in some sort his children, and to claim from them an allegiance in all matters pertaining to their health, which they at the most but very imperfectly recognise, and the binding nature of which they cannot therefore understand. But this relationship between men and their family practitioner is a very valuable one, and should be tenderly cherished. For I think there can be no doubt that the tendency in modern life is to change this old, and as I think salutary order of things. But, as I have already said, you may go to the great man in the town, but you still have a constitution or a temperament, of which you know little, and he may see nothing in one short interview. The three orders of medicine—medicine, surgery, and general practice—are still as necessary as ever they were. You may do without the last-named when there is nothing the matter with you, you may go to the specialists in town for an opinion on an obscure case, or to settle a moot point in treatment; but when one is really ill, then it is that you want, and cannot do without, the man with the cheery voice, the kindly smile, the deft hand, the many-sidedness of resource for easing pain born of long experience in many fields, and with it all the ready self-sacrifice that at times like these makes the medical

Digitized by Google

man almost seem to be "He that sticketh closer than a brother."

But I must stop. I have even now hardly more than indicated a few of the many points that my subject admitted of, but which were difficult to harmonise within the scope of the interest of an hour. Briefly put, my dominant idea is that man remains much too ignorant at the present day of the rudiments of the workings of his various parts. Thus it happens that at one time there is still a too blind faith in the power of the medical man, and at another time an equally blind intolerance and questioning of the restrictions and regulations that he, in his wisdom, feels called upon to impose. It would be much better for both parties concerned, and much more helpful to the art of healing, if medical man and patient could meet upon some common ground, and if the layman were able to follow the trains of thought that we may wish in some measure to make him understand, to realise in some small measure the great responsibility that medical men have to undertake. I do not suppose that this can be done to any great extent; in the case of the illness of those who are dear to us the issues involved are so tremendous to *us*; that to think on anything, much more on unfamiliar lines, becomes well-nigh impossible. Nevertheless, we should be better off if everyone had learned in some slight fashion to think upon the functions of their various parts and on the way in which those functions are conducted. There would then be less ignorance of the extreme intricacy of the subject; it would be more freely admitted that doubts must arise on all sides; and that watchfulness on the part of the medical man, and patience on the part of the sick man and of his relatives, are often the most important elements in successful treatment. The *Spectator* wrote the other day that "modern medicine discards more and more the old remedies of specific drugs, and relies more and more on the natural agencies, striving to reduce to a minimum artificial devices." And yet how much we see of the old order of things. The mass of mankind does not seem to me to have adequately kept up with this march of medical knowledge, and thus one is still too much in the seethe of excitement over the last new specific; the absolutely impossible is still deemed to be within the range of actual accomplishment; a medicine is still swallowed more as a charm than as a direct means to an end; and ignorance and shrewdness and the chances of life which happily mostly seem to make for health are together able to compete successfully with real knowledge. While this is so it can hardly be wondered at, life being so precious and tenacious as it is, that when common sense advice is tendered it is too likely to be met in the same spirit as of old. "Are not Abana and Pharpar, rivers of Damascus, better than all the waters of Israel? may I not wash in them, and be clean?" And the medical man out of the depths of a yearning disappointment at the apparent hopelessness of his contest against the competing forces is too often driven reproachfully to respond, "If the prophet had bid thee do some *great* thing, wouldest thou not have done it?"

SOME INTESTINAL EXPERIMENTS: A RAPID METHOD OF ENTERECTOMY.

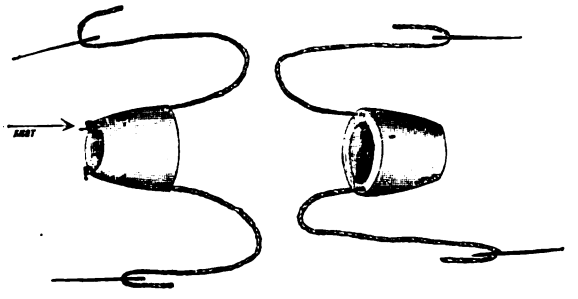
BY H. MARTYN JORDAN, F.R.C.S. ENG.,
LATE TEACHER OF OPERATIVE SURGERY AT H.H. THE NIZAM'S MEDICAL SCHOOL, HYDERABAD.

WHILST in India studying some of the tropical diseases I had the opportunity at Hyderabad of performing several different series of experiments on animals, one of which—on enterectomy—forms the subject of this paper. In this series my endeavour was to devise a rapid and safe method which would obviate: (1) the danger arising from the presence of the large metallic button and the risk of the gangrene spreading further than is necessary in Murphy's operation; (2) the time taken up in closing the two ends, making two new incisions and the presence of the three wounds of the bowel in Senn's method; (3) the two wounds of the gut and the perforation of all its layers by the twenty sutures in Maunsell's; and (4) the invagination or intussusception in Paul's. As the use of mechanical aids presents many advantages a digestible substance is needed to avoid the dangers of the metallic button, so decalcified bone and various vegetables were used; to avoid many sutures penetrating all the layers of the bowel it was necessary to find a suitable, rapid, and easy method of suturing which would only include the two outer layers; to have only one wound of the bowel it must be joined end to end. It may be mentioned here that the four operations just referred to were the only new methods of resection with which I was acquainted during these experiments; subsequently I learned of Mayo Robson's, and still later of its modifications by Allingham and Landerer.

Anatomy.—A short account of the anatomy of the dog's bowel may be desirable. It is rather less than one half the diameter of the human bowel; the peritoneal coat is very fragile and easily torn, and there is the usual triangular space at the mesenteric attachment. The vessels radiate from their origin and generally divide about three inches from the bowel into two or three branches, each of which again divides near the gut into two branches, which run in the apex of the triangular space at the mesenteric attachment, one upwards, the other downwards; the former joins the descending and the latter the ascending branches of the adjoining arteries; a chain of loops is thus formed parallel with the gut, and it is from this chain of loops that the terminal arteries are given off to supply the gut. These run transversely to the longitudinal axis of the bowel, some under the peritoneal, the majority in the muscular coat.

The general principle of my operation was adhered to throughout, but the details were modified from time to time for reasons which it may be well to relate briefly.

Incision.—The abdominal incision was made in the middle line in the first two cases—both dogs—but as the dressings and wound were continuously bathed in urine it was subsequently made—in dogs—in a direction obliquely downwards and inwards external to the deep epigastric artery. In bitches the median incision was always adopted.



Cones.—In order to bring the ends of the gut together and also to afford support during the suturing I used at first (Cases 1 to 6) two flat discs made from turnip, carrot, decalcified bone, &c. They were made very slightly greater in diameter than the lumen of the bowel, a quarter of an inch thick, with a large central hole and four sutures to each disc. One disc was passed in edgeways into each end of the bowel and rotated so as to lie transversely across the bowel, a fifth of an inch from the cut end. The four sutures were then passed through all the layers of the gut; the two ends of the gut were approximated and held in position by an assistant until the opposite or corresponding pairs of sutures were tied—i.e., mesenteric suture to mesenteric suture. The bowel over these discs being slightly raised allowed of easy suturing. But whilst the second disc was being inserted peristalsis had either expelled or so altered the position of the first that it had to be readjusted, and considerable time was thus lost, and even after the four pairs of sutures had been tied peristalsis caused the discs to lie obliquely. To overcome this clamps were placed across the bowel immediately above the discs when these were in position (Cases 3 to 6), and by the assistant keeping the four sutures tight the shifting was to a large extent controlled, and after the sutures had been tied the clamps kept the discs in position during the subsequent suturing, but the loops of the continuous suture used to unite the cut ends of the bowel repeatedly caught in one or other of the ends of the clamps and caused considerable delay. Owing to the time taken up in inserting and rotating these discs into position, the difficulty of retaining them in their position, and the further loss of time due to the catching of the suture round the clamps, these discs were discarded for two hollow cylinders, three quarters of an inch long, made from the decalcified femora of geese or turkeys. Two sutures were attached to each of these cylinders. These were easier to insert; the first was easily kept in position whilst the second was being inserted, and when the sutures had been passed through all the layers of the gut and the two opposite pairs tied no change of position could take place. As these cylinders required several days for their manufacture and allowed of but a very small amount of bevelling of one end, which is desirable in order to facilitate their insertion, they were subsequently made, immediately before the operation, from fresh carrots, turnips, or potatoes, in the form of a hollow, truncated cone (Cases 12 to 59), the apex being less than, and the base the diameter of, the lumen of the bowel. (Fig. 1). Each "cone" was furnished with two sutures, which were passed through its wall, from the apex to the base, one on each side; a big knot at the end of the suture (made

Digitized by Google

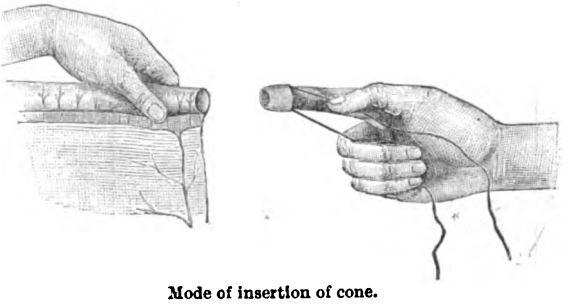
by passing the end six or seven times through the loop before drawing tight) prevented the suture being pulled through the cone. They answered extremely well and were most rapidly and easily inserted.

Sutures.—Lembert's and Halstead's interrupted sutures were used in Cases 1 to 4 and 16 to 18 respectively, but were discarded for a more expeditious method. A "button-hole" suture was employed (Cases 5 to 15 and 19) but rejected because (1) it was difficult to avoid tearing through the very delicate peritoneal coat when drawing the transverse loops tight; and (2) the needle had to be inserted in the line of the longitudinal axis of the bowel, and

FIG. 1.

Cones with sutures and needles attached.

it was impossible to avoid at times wounding the terminal branches of the mesenteric artery running transversely to the axis in the muscular coat, as these cannot be seen. In three cases (Cases 6, 13, and 15) these vessels were transfixed and had to be underpinned. All three died, and one death (Case 13) was clearly due to the ligaturing of this artery. 3. In drawing the loops sufficiently tightly together the blood-flow in those arteries included in the loops was retarded and union thus delayed. On the whole it is an excellent and rapid stitch, and by a little manœuvring (pulling the needle towards the last loop until the new loop is sufficiently tight) the first objection can be generally avoided. The second and third objections—transfixion and retarded blood-flow—rendered it desirable that the needle during its passages through the wall of the bowel should be parallel to the terminal vessels. An ordinary overhand continuous suture was tried (Cases 20 and 21) and rejected on account of the slight puckering of the serous coat, and because the needle had to be inserted at right angles to the vessels. In consequence the following suture was tried. A needle was threaded on each end of some fine Chinese twist silk; one needle was inserted an eighth of an inch from the cut margin of the bowel and passed along parallel with it for one-eighth of an inch through the serous and muscular coats only, the other needle was then used similarly on the other cut end, the entry and exit of the two needles being opposite one another respectively. The suture was drawn through equally on both sides and the right hand needle then brought over the cut margins and inserted close to the exit of the left and used as before; the left needle was in like manner inserted on the right side. In this way the bowel was rapidly surrounded, the edges being inverted as the stitches were drawn tight. This suture is unsafe and was only employed twice (Cases 22 and 23); both operations were performed on the same day and both dogs died two days after. The post-mortem examination in each case showed that the suture had tightened on one side and loosened on the other and that extravasation had taken place where the suture had opened out.[1] The suture was therefore modified by a reef knot being tied each time the two needles were brought out. This answered very well and the whole circumference could be surrounded in a few minutes (Cases 24 to 26). Experience proved, however, that a double turn was as efficacious as the knot, and as it saved time it was employed from Case 27 to the end. It is advisable to have two or more of these "two-needled" sutures at hand.



Needles.—Various forms of needles were used for suturing the bowel. It was found that small, round, straight needles with fairly big eyes were best adapted for this purpose; they are easier to use than the curved as they do not rotate or slip between the fingers and are very easily inserted over the convex surface of the cone.

Graft.—An omental graft was applied around the bowel at the site of resection in thirteen of my cases and in three of Dr. Conolly's. It was omitted in all the subsequent cases for reasons which will be fully discussed under the heading of "Remarks."

Mesentery.—A wedge-shaped portion of the mesentery was always removed. It was found that the nearer the edges were to the adjoining arteries the better was the result. The triangular spaces at the mesenteric attachment were closed and brought together by a separate suture. In Case 24 this was not done, and when the dog was subsequently killed a hole was found in the mesentery large enough for another coil to have slipped through.

Operation.—Having thus recounted the changes in the details from time to time the operation as performed in all my later cases (Cases 27 to 59) will now be described. The dog having been chloroformed, the abdomen shaved, and carefully washed, an incision was made two inches long and all the bleeding stopped before opening the peritoneum. The gut to be excised was brought up through a hole in an antiseptic towel and carefully packed all round with sponges. The branch or branches of the mesenteric artery running to the portion of gut to be removed were secured by thrusting the points of a pair of Spencer Wells's forceps through the mesentery on either side of the artery from two and a half to three inches from the bowel; then with two pairs of Spencer Wells's forceps the arterial loops running in the triangular space at the mesenteric attachment were secured in the same way on a level with the points at which it was decided to resect the bowel.[2] The bowel was then divided at right angles to its longitudinal axis with scissors over a large flat sponge on a level with the two latter pairs of forceps, of course on the occluded side of the arteries. By continuing these cuts to the first pair of forceps a wedge-shaped portion of mesentery was removed. The three arteries were then ligatured. The section of the gut caused great contraction of the circular and longitudinal muscle, resulting in great narrowing of the lumen by the former and protrusion of the mucous coat by the latter. This was overcome by the insertion of the tip of the little finger, on withdrawing which one of the cones was at once inserted, apex first (see Fig. 2),

FIG. 2.

Mode of insertion of cone.

and the "cone-sutures" were passed through all the layers of the bowel an eighth of an inch from the cut margin, one at the mesenteric attachment and the other at the opposite side of the gut. The other cone was similarly passed and, both being in position, the assistant approximated the ends of the bowel and the corresponding pairs of sutures were tied moderately tightly. The ends of the sutures were cut as short as possible. The cut ends of the gut were thus fixed in contact, slight inversion of the ends occurring at the two sutures. The bowel was then rotated on its longitudinal axis so as to bring the mesenteric attachment forwards and nearly half an inch of the under side of the gut into view through the severed edges of the mesentery (this was done in order that the mesenteric attachment, the most difficult portion, might be sutured first). The continuous

[1] Since this paper was written I have seen in Treves's "Operative Surgery" that this suture was devised by Gély. In my opinion it is an unreliable suture for the reason above stated.

[2] This method of dealing with the arteries proved to be much more satisfactory than the usual way, and it is much to be preferred to that of dividing the arteries first and picking them up afterwards, as the whole operation is bloodless. Rarely a small muscular branch opposite the mesenteric attachment and running in the direction of the axis of the bowel was found and needed ligature; there is always an artery in this position at the upper portion of the jejunum.

TABULAR STATEMENT OF CASES.

Case.	Date of operation.	Sex and condition.	Incision.	Length of intestine excised.	Form of disc, cone, &c.	Suture used to unite bowel.	Graft.	Time taken by operation from skin incision to last parietal suture.	Remarks.
1	Aug. 15th, 1895.	Large healthy male. Tapeworms.	Median	2 in.	Discs of decalcified bone	Lembert's	Graft	1 hour	Continual shifting of discs caused great delay. Evisceration during vomiting and intestine urinated over. Hypodermic injection of morphia ¼ gr. Died on the fourth day. *Necropsy.*—No peritonitis except over graft, which was adherent to three coils of intestine. No extravasation. Union of gut firm all round. Lumen diminished about one-third. No obvious cause of death.
2	Aug. 18th, 1895.	Emaciated, unhealthy male. Tapeworms.	Median	6 in.	Discs of turnip	Lembert's	Graft	1 hour	Same difficulty with discs and evisceration during vomiting. Hypodermic injection of morphia ¼ gr. Killed by overdose of chloroform on ninth day. *Necropsy.*—No peritonitis. Graft adherent to two other coils. Lumen reduced about one-third. Wound of gut firmly united. Partial occlusion due to acute bending by adhesions.
3	Aug. 25th, 1895.	Unhealthy male. Bowel full of tapeworms.	Lateral	6 in.	Discs of decalcified bone	Lembert's	Graft	45 min.	Clamps were used to check shifting of discs. Lateral incision to avoid dog urinating on dressings and wound. Hypodermic injection of morphia ¼ gr. During the first two months the dog did well and grew fat and big. Signs of obstruction then appeared. (Vide text for further particulars.)
4	Aug. 26th, 1895.	Medium sized male.	Lateral	3 in.	Discs of decalcified bone	Lembert's	Graft	50 min.	Discs slightly too large. Clamps again used. Loop of artery at mesenteric attachment was transfixed and ligatured. Hypodermic injection of morphia ¼ gr. Died on the fourth day. *Necropsy.*—Gangrene of end of bowel over disc on the side of the ligatured arterial loop. Graft adherent to two other coils.
5	Aug. 30th, 1895.	Emaciated male. Tapeworms.	Lateral	4 in.	Discs of turnip	Button-hole	Graft	50 min.	Suture more rapid than Lembert's, but loops continually caught in clamps and tore through in three places. Hypodermic injection of morphia ¼ gr. Excellent recovery.
6	Sept. 3rd, 1895.	Healthy male. Tapeworms.	Lateral	4 in.	Discs of decalcified bone	Button-hole	Graft	50 min.	Transfixed small muscular branch of artery, which had to be underpinned. Hypodermic injection of morphia ¼ gr. Died on the fourth day. *Necropsy.*—Peritonitis, extravasation along mesenteric disc-suture and under and through graft. Line of union sound except at this point. Graft adherent to two coils.
7	Sept. 5th, 1895.	Healthy male.	Lateral	6 in.	Cylinders of decalcified bone with two sutures to each	Button-hole	Graft	40 min.	Cylinders easier to insert, kept in position most easily by assistant's finger, and after the two pairs of sutures were tied no change in position took place. Clamps were not used. Hypodermic injection of morphia ¼ gr. Died eight hours after, possibly due to large dose of morphia; its use was abandoned in all subsequent cases. The line of resection was watertight.
8	Sept. 6th, 1895.	Small, unhealthy male. Tapeworms.	Lateral	3 in.	Cylinders as in No. 7	Button-hole	Graft	38 min.	Killed on the sixth day. *Necropsy.*—The graft was adherent to three other coils. The gut was firmly united. Contraction of graft had greatly reduced the lumen of the bowel and also caused an annular fold of its wall.
9	Sept. 8th, 1895.	Small male.	Lateral	3 in.	Cylinders (slightly bevelled at one end)	Button-hole	Graft	28 min.	The bevelling of the cylinders facilitated their insertion. The suture tore through in one place. Dog did well until the fourth day, then refused food and seemed poorly; the abdomen was hard and retracted. Whilst an exploratory incision was being made respiration ceased, and all attempts to restore it failed. The heart beat for 2½ min. after respiration ceased. *Necropsy.*—No peritonitis except over graft, which was adherent to three other coils. The gut was firmly united all round; the lumen was slightly diminished.

TABULAR STATEMENT OF CASES—*Continued.*

Case.	Date of operation.	Sex and condition.	Incision.	Length of intestine excised.	Form of disc, cone, &c.	Suture used to unite bowel.	Graft.	Time taken by operation from skin incision to last parietal suture	Remarks.
10	Sept. 12th, 1895.	Emaciated female Tapeworms.	Median	4 in.	Cylinders as in No. 9	Button-hole	Not used	30 min.	Suture tore through in two places. On March 3rd, 1896, the bitch gave birth to a litter of six pups. The bitch was much larger and healthier. On May 5th, 1896, half the spleen was excised (vide Case 9, "Conservative Surgery of the Spleen"). The bowel was inspected, and the site of resection was indistinguishable from the rest of the gut but for one thin adhesion.
11	Sept. 13th, 1895.	Healthy female.	Median	2 in.	Cylinders as in No. 9	Button-hole	Graft	28 min.	Excellent recovery. On April 29th, 1896, the bitch deserted.
12	Sept. 18th, 1895.	Large male. Tapeworms.	Lateral	5 in.	Hollow truncated cones made from carrot	Button-hole	Graft	25 min.	Cones much more easily inserted. Dog did well. Killed on the sixth day. *Necropsy.*—Graft was adherent to two other coils. About ten drops of pus under graft at mesenteric attachment. Cone-suture knot was lying in this cavity. Partial occlusion by acute bending due to adhesions; lumen was also contracted by graft, which had also caused a small annular fold of the wall.
13	Sept. 20th, 1895.	Large female. Tapeworms.	Median	3 in.	Cones as in No. 12	Button-hole	Graft	30 min.	During the suturing a muscular branch was transfixed and had to be underpinned. Died on the third day. *Necropsy.*—General peritonitis—gangrene of that portion of margin to which the underpinned artery went. Graft was adherent to two coils.
14	Sept. 22nd, 1895.	Healthy male.	Lateral	6 in.	Cones	Button-hole	Graft	35 min.	Dog extremely savage and violent, chained to stake. On the third day free hæmorrhage from wound; exploration revealed a very large spleen, torn almost in two. It was killed; the union of gut was firm. Graft was adherent to two other coils.
15	Sept. 25th, 1895.	Large male. Tapeworms.	Lateral	12 in.	Cones	Button-hole	Not used	24 min	During the suturing a muscular branch was transfixed and underpinned. Died on the fifth day. *Necropsy*—General peritonitis, extravasation along mesenteric cone, suture.
16	Sept. 25th, 1895.	Medium-size male. Tapeworms.	Lateral	10 in.	Cones	Halstead's	Not used	30 min.	Excellent recovery.
17	Sept. 27th, 1895.	Healthy female.	Lateral	13 in.	Cones	Halstead's	Not used	30 min.	Pregnant at time of operation; condition found after the abdomen was opened. On Nov. 11th, 1895, she gave birth to a litter of six pups. Excellent recovery.
18	Sept. 28th, 1895.	Large healthy male.	Lateral	5 in.	Cones	Halstead's	Not used	22 min.	Uninterrupted recovery. Killed on the twenty-seventh day. *Necropsy.*—One coil was loosely adherent to line of resection. Union of gut was perfect. Calibre was that of the rest of the bowel.
19	Sept. 30th, 1895.	Healthy female.	Median	2 in.	Cones	Button-hole	Not used	28 min.	Excellent recovery.
20	Oct. 2nd, 1895.	Female.	Median	6 in.	Cones	Overhand continuous	Not used	22 min.	Suture caused slight puckering of serous coat. Excellent recovery.
21	Oct. 5th, 1895.	Healthy male.	Lateral	9 in.	Cones	Overhand continuous	Not used	25 min.	Suture caused slight puckering of serous coat. Excellent recovery.
22	Oct. 7th, 1895.	Small healthy male. Tapeworms.	Lateral	8 in.	Cones	Double-needled crossed suture	Not used	20 min.	Very rapid suture. Died on the third day. *Necropsy.*—General peritonitis; extravasation through small opening in line of resection where the stitch had "opened out."
23	Oct. 7th, 1895.	Unhealthy female. Tapeworms.	Median	6 in.	Cones	Same as No. 22	Not used	18 min.	Died on the third day. *Necropsy.*—Same as in No. 22.
24	Oct. 11th, 1895.	Small female. Tapeworms.	Median	14 in.	Cones	Knotted crossed	Not used	28 min. (delayed by artificial respiration)	Rapid suture; dog did well. Killed on the seventh day. *Necropsy.*—Perfect union of gut, small opening in mesentery close to bowel.
25	Oct. 12th, 1895.	Unhealthy emaciated male. Tapeworms.	Lateral	6 in.	Cones	Same as in No. 24	Not used	18 min.	Excellent recovery.

TABULAR STATEMENT OF CASES—*Continued.*

Case.	Date of operation.	Sex and condition.	Incision.	Length of intestine excised.	Form of disc, cone, &c.	Suture used to unite bowel.	Graft.	Time taken by operation from skin incision to last parietal suture.	Remarks.
26	Oct. 13th, 1895.	Small emaciated female. Tapeworms.	Median	15 in.	Cones	Same as in No. 24	Not used	18 min.	Bowel full of tapeworms. Died on the fourth day. *Necropsy.*—General peritonitis; extravasation along the cone-suture opposite the mesenteric attachment, the ends of which had not been cut short enough or properly inverted. They lay between the two inverted margins of the gut and were included in one of the loops of the crossed suture. The bowel immediately around this suture was softened and the peritoneum separated by exudation from the muscular coat.
27	Oct. 15th, 1895.	Very small male.	Lateral	12 in.	Cones	Crossed with two turns instead of the knot	Not used	28 min. (twice delayed by artificial respiration)	Uninterrupted recovery. Dog grew big and fat. Killed on March 25th, 1896 (161st day). *Necropsy.*—Bowel was adherent to one other coil. This and the two mesenteric branches being parallel and close together were the only indications of the line of resection. The lumen was that of the rest of the bowel.
28	Oct. 16th, 1895.	Medium size female.	Median	9 in.	Cones	Same as No. 26	Not used	19 min.	Excellent recovery.
29	Oct. 17th, 1895.	Medium size male. Tapeworms.	Lateral	15 in.	Cones	Same as No. 26	Not used	20 min.	Dog did well. Killed on the ninth day. *Necropsy.*—Line of union was perfect, adherent to one other coil. "Cone sutures" still lying on mucous surface.
30	Oct. 18th, 1895.	Healthy female.	Median	14 in	Cones	Same	Not used	19 min.	Excellent recovery.
31	Oct. 20th, 1895.	Large violent male.	Lateral	8 in.	Cones	Same	Not used	18 min.	Dog being very violent was chained to a stake. On the fifth day—twenty minutes after I had seen him fed—I was called and found that the dog had impaled himself on the stake, torn open the parietal wound, and that the intestine had got entangled round his legs and the stake and was torn in pieces. An overdose of chloroform was at once given, when it was seen that the dog had almost completely disembowelled himself.
32	Oct. 24th, 1895.	Emaciated male. Tapeworms.	Lateral	13 in.	Cones	Same	Not used	19 min.	Uninterrupted recovery. Killed on the nineteenth day. *Necropsy.*—Resected bowel was adherent by one thin band to parietes; no banding of gut. Line of union was perfect. Lumen was undiminished. One cone-suture was still adherent.
33	Oct. 30th, 1896.	Healthy female.	Median	6 in.	Cones	Same	Not used	17 min.	Pregnant at time of operation. Condition only discovered after abdomen was opened. On Dec. 20th the bitch gave birth to a litter of five pups. Excellent recovery.
34	Nov. 6th, 1895.	Small unhealthy male. Tapeworms.	Lateral	6 in.	Cones	Same	Not used	19 min.	Dog did very well. Killed on the seventh day. *Necropsy.*—Line of resection firmly united. The lumen was very slightly diminished.
35	Nov. 9th, 1896.	Healthy female.	Median	9 in.	Cones	Same	Not used	18 min.	Excellent recovery.
36	Nov. 14th, 1895.	Small emaciated male. Tapeworms.	Lateral	15 in.	Cones	Same	Not used	19 min.	Excellent recovery. Grew fat and big.
37	Nov. 20th, 1895.	Healthy male.	Lateral	4 in.	Cones	Same	Not used	22 min.	Kidney was also removed. Dog the same evening appeared comfortable and was walking about. Died the next day. *Necropsy.*—There was no peritonitis except at site of resection, which was covered by a layer of plastic lymph and was watertight. The renal pedicle was perfectly occluded.
38	Nov. 24th, 1895.	Healthy female.	Median	13 in.	Cones	Same	Not used	18 min.	Excellent recovery.
39	Nov. 27th, 1895.	Emaciated unhealthy female. Tapeworms.	Median	5 in.	Cones	Same	Not used	19 min.	Excellent recovery.
40	Nov. 30th, 1895.	Healthy male.	Lateral	14 in.	Cones	Same	Not used	17 min.	Excellent recovery.
41	Dec. 4th, 1895.	Healthy male.	Lateral	12 in.	Cones	Same	Not used	18 min.	Excellent recovery
42	Dec. 5th, 1895.	Healthy male.	Lateral	9 in.	Cones	Same	Not used	19 min.	Excellent recovery.
43	Dec. 8th, 1895.	Large female.	Median	10 in.	Cones	Same	Not used	18 min.	Excellent recovery. On May 5th, 1896, the bitch gave birth to a litter of five pups.

TABULAR STATEMENT OF CASES—*Continued.*

Case.	Date of operation.	Sex and condition.	Incision.	Length of intestine excised.	Form of disc, cone, &c.	Suture used to unite bowel.	Graft.	Time taken by operation from skin incision to last parietal suture.	Remarks.
44	Dec. 12th, 1895.	Small male. Tapeworms.	Lateral	8 in.	Cones	Same	Not used	18 min.	Excellent recovery.
45	Dec. 17th, 1895.	Emaciated female. Tapeworms.	Median	10 in.	Cones	Same	Not used	18 min.	Excellent recovery.
46	Dec. 23th, 1895.	Healthy male.	Lateral	16 in.	Cones	Same	Not used	19 min.	Dog did very well. Killed on Jan. 17th, 1896 (23rd day). *Necropsy.*—Line of resection loosely adherent to one other coil, this and the two mesenteric branches being close together and parallel were the only indications as to the exact line of union. On further searching at the mesenteric attachment a short length of suture was found. Lumen was undiminished.
47	Dec. 30th, 1895.	Medium sized female Tapeworms.	Median	4 in.	Cones	Same	Not used	17 min.	Excellent recovery.
48	Jan. 3rd, 1896.	Small male.	Lateral	6 in.	Cones	Same	Not used	18 min.	Excellent recovery.
49	Jan. 14th, 1896.	Healthy male.	Lateral	9 in.	Cones	Same	Not used	17 min.	Excellent recovery.
50	Jan. 16th, 1896.	Small female. Tapeworms.	Median	4 in.	Cones	Same	Not used	19 min.	Died on the 8th day. *Necropsy.*—Centre of abdominal wound communicated with peritoneal cavity. General peritonitis. No sign of extravasation. Union of gut quite sound.
51	Jan. 20th, 1896.	Healthy female.	Median	12 in.	Cones	Same	Not used	18 min.	Excellent recovery.
52	Jan. 27th, 1893.	Emaciated male.	Lateral	3 in.	Cones	Same	Not used	19 min.	Excellent recovery.
53	Feb. 2nd, 1896.	Male.	Lateral	8 in.	Cones	Same	Not used	17 min.	Excellent recovery.
54	Feb. 6th, 1896.	Emaciated female. Tapeworms.	Median	6 in.	Cones	Same	Not used	20 min.	Delayed by artificial respiration, and cone-sutures becoming entangled. Excellent recovery.

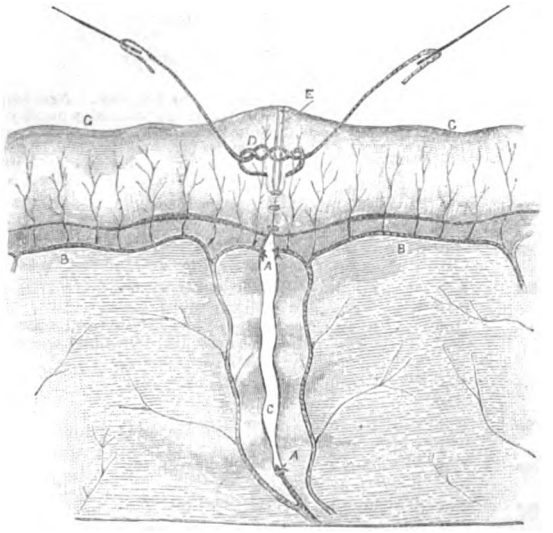
56	Feb. 16th, 1896.	Small male.	Lateral	3 in.	Cones	Same	Not used	16 min.	Excellent recovery.
57	Feb. 25th, 1896.	Healthy female.	Median	13 in.	Cones	Same	Not used	18 min.	Excellent recovery.
58	Feb. 28th, 1896.	Emaciated female.	Median	9 in.	Cones	Same	Not used	17 min.	Excellent recovery.
59	March 4th, 1896.	Healthy female.	Median	4 in.	Cones	Same	Not used	16 min.	Excellent recovery.



DR. CONOLLY'S CASES (OPERATED UPON DURING NOVEMBER AND DECEMBER, 1895).

Case.	Sex and condition.	Incision.	Length of intestine excised.	Cones.	Suture used to unite bowel.	Graft.	Remarks.
1	Large female.	Median	3 in.	Cones	Button-hole	Not used	Dog took chloroform badly and operation was interrupted twice. After the gut had been sutured all round it was discovered that one end had been rotated through a whole circle, a very severe kink being the result. It was decided to leave the necessary resection for a few days, and so no graft was used. On the fourth day Dr. Conolly reopened the abdomen and excised 6 in. of intestine, including the old line of union, which was firmly united. It died next day. The line of union was water-tight.
	—	—	6 in.	,,	,,	Graft	
2	Large healthy male.	Lateral	5 in.	Cones	Button-hole	Graft	Dog did very well. Killed three weeks after operation. *Necropsy.*—Graft was adherent to two other coils, and also to same coil about 2 in. from line of union; its contraction had caused an acute bend of the gut and partial occlusion. There were no symptoms of obstruction during life.
3	Small unhealthy male. Tapeworms.	Lateral	3 in.	Cones	Cross knotted	Graft	Dog did well. Killed on the fifth day. Graft, which was adherent to two other coils, was carefully removed; gut firmly united; cones not quite absorbed.
	Medium size male.	Lateral	12 in.	Cones	Cross knotted	Not used	Excellent recovery.
5	Small healthy female Tapeworms.	Median	4 in.	Cones	Crossed double-turned	Not used	Excellent recovery. On May 4th, 1896, the bitch gave birth to a litter of six pups.
6	Healthy female.	Median	2 in.	Cones	Same as No. 5	Not used	Excellent recovery.
7	Medium size male.	Lateral	3 in.	Cones	Same	Not used	Excellent recovery
8	Small emaciated female Tapeworms.	Median	14 in.	Cones	Same	Not used	Excellent recovery. Dog grew big and fat.

Digitized by Google

"double-turned" suture previously described was commenced on the under surface of the bowel about one-third of an inch from the mesenteric attachment; especial care was paid to the first four stitches (which take in this attachment) to ensure that the knot of the "cone-sutures" was buried beneath the line of the continuous suture. To effect this the needles were here inserted a little farther from the cut margins. The assistant, holding the bowel at the apex of each "cone" between the thumb and first two fingers of each hand, kept the cut ends of the gut in view (otherwise excessive inversion occurred during the suturing) and gradually rotated the bowel back to its original position as the suturing proceeded. When the opposite "cone-suture" knot was reached the same care to conceal it was bestowed as upon the former one. This especial care to conceal or bury the "cone-suture" knots beneath the continuous suture is imperative, as three of the cases (Cases 6, 15, and 26) died from general peritonitis due to extravasation along the "cone suture," but this was prevented in the subsequent cases (Cases 27 and 49) by this extra care being bestowed upon the knots. As each "double turn" (see Fig. 3) of the continuous suture was in

FIG. 3.

Operation half completed (dog's bowel). A, A, Arteries ligatured. B, B, Arterial loops. C, Gap in mesentery. D, Double turn. E, Cut margins of gut. G, G, Gut.

process of being tightened the assistant, with the closed blades of a pair of scissors applied on the flat, or other instrument, inverted the margins of the bowel and kept them so until the double turn was drawn sufficiently tight to invert them permanently. When the gut had been sutured all round the two ends of the suture were tied with a reef knot; the bowel was then carefully cleansed and the line of resection inspected to ensure that the edges were everywhere inverted. If at any point this was not so a stitch or two with a spare "double-needled" suture was taken. The margins being everywhere inverted the gap in the mesentery was closed with one end of the original "double-turned" suture by an overhand continuous stitch. With the other end of the suture, or if preferred an extra suture in a curved needle (the latter is more easily passed), a stitch was taken through both margins of the mesentery close to the bowel; when this was tied it closed and also brought together the two triangular spaces at the mesenteric attachment; but care must be taken in passing this stitch not to wound the arterial loops running in the apices of these spaces, as on them depends the vitality of the ends of the gut. (*Vide* Case 4.) The gut was then bathed in hot water and returned; the peritoneal and the three muscular coats of the abdominal wall were severally united with an overhand continuous suture, and, lastly, the subcutaneous tissue was sutured over all. As these dogs could not be kept quiet and primary union was almost impossible to attain the skin wound was not closed, and all dressings were abandoned after the first nine or ten cases; the wound was kept clean by the dog licking it, and it healed very rapidly. The suture in the subcutaneous tissue was removed about the fourth day.

After-treatment.—The diet of the dogs was confined as far as possible to milk for the first two days, the dogs being allowed as much as they would drink; for the next four days minced meat and boiled rice were substituted, and they were then allowed to eat anything; but as the dogs were unfettered many of them obtained solid food surreptitiously in the first few days. A few of the earlier cases were given a quarter of a grain of morphia subcutaneously immediately after the operation; this was advantageously discontinued.

Remarks.—The number of dogs upon which I personally performed resection was 59. These may be considered under three headings:—

I. Those cases where "discs" were used. The number operated upon was 6 (Cases 1 to 6), with 3 deaths. 1. Case 1, on the fourth day. At the necropsy the line of union was perfect, and there was no apparent cause of death. 2. Case 4, on the fourth day. At the necropsy gangrene of one margin was found. At the operation the arterial loop at the mesenteric attachment was transfixed and ligatured and the discs were slightly too large. The gangrene was on the same side as the ligatured artery. 3. Case 6, on the fourth day. At the necropsy peritonitis and extravasation along the "disc-suture" and through the graft were found. This gives a mortality of 50 per cent., but the first death might be eliminated as the dog had recovered from shock, the gut was perfectly united, no peritonitis was present, and there was reason to believe that the dog was poisoned.

II. Those cases where "cylinders" or "cones" were used, but various kinds of sutures experimented with. The number operated upon was 20 (Cases 7 to 26 inclusive), with 6 deaths. 1. Case 7, eight hours after operation. Death was caused by shock or the effect of half a grain of morphia injected unknown to me. The line of resection was watertight. 2. Case 13, on the third day. At the necropsy gangrene of a small portion of one margin due to the underpinning of a transfixed arterial twig was found. 3. Case 15, on the fifth day. At the necropsy peritonitis and extravasation along the cone suture were found. 4 and 5. Cases 22 and 23, on the third day. At the necropsies peritonitis and extravasation through a small opening in the line of resection were found. These two cases were those in which the unknotted crossed sutures were used. 6. Case 26, on the fourth day. At the necropsy peritonitis and extravasation along the cone suture were found. The mortality in this series was 30 per cent.

III. Those cases operated upon in the manner described—i.e., with cones and the suture finally adopted. The number operated upon was thirty-two[3] (27 to the end) with 2 deaths. 1. Case 37, twenty-four hours after operation; in this case the kidney was also removed. The dog was walking about the evening of the operation and seemed comfortable. At the necropsy the line of resection was found to be watertight. 2. Case 50, on the eighth day. At the necropsy the abdominal wound was found to communicate with the peritoneal cavity. There was general peritonitis; the union of the gut was perfect. This gives a mortality of 6·2 per cent., but Case 50 should be eliminated, as where primary union can be depended upon (in the case of a human being) no such result would happen; and in a total of 105 dogs, of which the above 59 form part, all of which had to be allowed to run about freely without any dressings, this was the only case in which leakage backwards from the abdominal wound occurred. If this case therefore be excluded the mortality would be 3·1 per cent. But in speaking of this mortality of 3·1 per cent. it should be remembered that two of the cases (Cases 29 and 34) were killed on the seventh and ninth days respectively in order to see the condition of the gut operated upon and perhaps before all danger had passed, but from the condition found—the gut perfectly united in both cases—complete recovery seemed to be assured. It must also be borne in mind that the dogs were not suffering from obstruction and that in cases of obstruction the degree of success will depend largely upon the state of the patient at the time of operation. But I believe that I should be correct in stating that if conditions were similar better results would be obtained in man, as the operation is easier, the gut more readily manipulated, the peritoneal coat not so fragile, and—a most important point—

[3] Case 31 is omitted from the following considerations, as the dog disemboweled himself on the fifth day, and such a result cannot be attributed to the operation.

the patient can subsequently be kept absolutely at rest on a suitable diet and rapid union ensured.

It may be mentioned here that Dr. Waldo Conolly, of Melbourne, who was at Hyderabad studying Lawrie's method of chloroform administration, assisted me in several of these experiments. He performed resection on four dogs by Senn's method; each operation lasted a little over one hour, and all four died from extravasation. He subsequently operated upon eight dogs by my method. In the first operation, after the bowel had been sutured all round, it was seen that one end of the gut had been rotated through a whole circle, a very severe kink being the result. As the dog had been under operation forty-five minutes, and to have resected this kink would, at the same rate, have taken another forty-five minutes, it was decided to postpone the further operation. On the fourth day Dr. Conolly reopened the abdomen and excised six inches of gut, the old line of resection which was firmly united being in the centre. The dog died next day from shock. The remaining seven cases all made uninterrupted recoveries, and the mortality, which would have been *nil* but for this unfortunate misadventure, is, therefore, 12·5 per cent. for Dr. Conolly's series.

As previously stated, a graft was applied in sixteen cases, but afterwards omitted. In every case where it was used and the dog subsequently died or was killed (Cases 1, 2, 3, 4, 7, 8, 9, 12, 13, and 15 of my series, and Cases 2 and 3 of Dr. Conolly's) the necropsy showed that: 1. In cases examined shortly after operation the graft, which had consisted of a thin single layer of omentum, had become greatly thickened by inflammatory exudation and formed a band a quarter of an inch thick round the bowel. In cases examined at a later period this band had become converted into a thick fibrous ring. 2 The graft had formed very firm and extensive adhesions with other coils of intestine, matting them together in such a way as to render their separation difficult and in one of my cases (Case 3) and one of Dr. Conolly's (Case 2) impracticable. 3 Contraction of the graft circularly had resulted in a very considerable narrowing of the lumen of the bowel (see Fig. 4). 4. Contraction of the graft longitudinally had caused large

FIG. 4.

Longitudinal section of gut, showing constriction caused by contraction of graft. A, Graft greatly thickened. B, Cone-sutures on mucous surface. C, Line of union (this is drawn much too distinct, in the specimen it was only just visible). D, Annular fold of wall due to contraction of graft.

annular folds of the wall of the bowel, which still further reduced the lumen. 5. In three cases partial, and in one complete, occlusion by acute bending of the gut had been caused. That the omental graft may be a safeguard against extravasation is shown by Case 12; but in Case 6, in which the dog died on the fourth day from peritonitis due to extravasation along a "disc suture" and then under and through the graft, also shows that but little reliance can be placed upon it and its disadvantages more than outweigh this one advantage. There is but little doubt that had these dogs been allowed to live some, at least, of them would have shown signs of obstruction later, and where a graft has been employed and obstruction subsequently supervenes relief will, in the great majority of cases, be impossible in consequence of the number of other coils of intestine involved by the graft. Case 3 illustrates this almost hopeless condition very well; the dog had made an uninterrupted recovery and remained in good health for two months after the operation, but then began to lose its appetite, to vomit after food, and to lose weight. The abdomen was reopened with a view to resecting the strictured gut, but it was found that five coils of intestine were matted together by such dense adhesions and in such a way as to render their separation impossible. If the whole had been removed the dog would have been left practically intestineless, so an overdose of chloroform was given. Even after death, so dense were the adhesions and so changed and twisted was the gut that the separation of the coils was most difficult; contraction of the graft had reduced the lumen by more than one-half, a large annular fold of the wall had been caused by the longitudinal contraction, and occlusion of the gut from acute bending by the adhesions was also present. A lateral anastomosis might have been performed in this case, but I opined that the dog would die from marasmus as very little intestine could be left free, and so to save suffering the dog was killed. In man, with his very much longer intestine, this operation would in these cases present the best hope.

In addition to these grave objections to the use of the graft there are also: (1) the constant danger of internal strangulation from the presence of these adhesions between the graft and surrounding parts; (2) the acute paroxysmal pain; or (3) the chronic discomfort, ending in a more or less complete disability, from dragging on the adhesions. It will be seen in the tabular statement that two dogs in which the graft was used (Cases 5 and 11) were apparently in good health eleven and seven months respectively after operation. In these cases the most that can be said is that the graft did not produce obstruction, but it cannot be said, of course, that the dogs did not suffer inconvenience or pain. But even granting that in some cases the graft may prevent extravasation and that in a few no obvious ill results follow, its employment is attended by so many and such serious objections that its use is to be condemned and reliance placed entirely upon a careful suturing.

The operation as described is rapid, occupying less than twenty minutes from the skin incision to the last parietal suture. Only two sutures penetrate all the layers of the bowel, and these are subsequently buried and shut off from the peritoneal cavity. There is only one wound of the bowel, and this wound is supported and protected during its union by the cones until their absorption. The "cones" are most easily inserted in consequence of their shape; their calibre is large, thus allowing an immediate and free channel for the passage of fæces past the line of resection without undue strain on the gut; they are dissolved in from three to four days and can be readily and rapidly made anywhere. Of the various vegetables tried fresh carrots were found to be the best as they were stiffer and firmer—if made of some other suitable material the cones could be kept in stock of all sizes; they also afford a firm convex background for the suturing, and the portion of the gut that has to be sutured being raised above the rest permits of this being done more easily than can be the case when the suturing takes place transversely to the long axis at the bottom of a depression, as in Mayo Robson's operation. The suture is a very rapid one; the fact that the needles are inserted parallel to the blood-vessels greatly diminishes the risk of these being transfixed and also prevents interference with the flow of blood through them; it allows of a firm hold being taken on the bowel, and the stitches do not cut through nearly so readily as when made longitudinally; the mucous coat is not involved and risk of extravasation along the suture is thus avoided. Each loop must be drawn only sufficiently tight to keep the edges inverted, if drawn too tight pressure-atrophy occurs and union is delayed as is the case with any form of intestinal suture. With an able assistant the suturing of the bowel can be completed in less than four minutes. Whilst I believe this suture to be the best for all transverse wounds of the bowel it would not be so applicable for longitudinal wounds. At the time of the operation the lumen of the bowel is only slightly diminished, and no contraction of the scar takes place subsequently. The tendency that exists for the mucous coat to extrude is prevented reaching a dangerous degree by the continuous suture, and the slight degree that does take place is beneficial as it allows of end-to-end union of this coat. The operation as described has been for an end-to-end apposition, but it is as applicable for an end-to-side union if one cone and a perforated disc of the same diameter as the base of the cone are used; in every other respect the operation would be the same. For a side-to-side apposition two perforated discs would be used. This would be a modification of Senn's method, the differences being the shape of the discs, two disc-sutures instead of four, and a buried continuous suture instead of an omental graft.

Of all the dogs operated upon 39 per cent. had tapeworms, and freeing the ends of the gut from these delayed the operation somewhat. These worms are also a source of danger in

Digitized by Google

the operation, as 66 per cent. of the deaths occurred in dogs afflicted with tapeworms. The three dogs that died from extravasation along the cone or disc-sutures all had tapeworms, and in Case 12 (in which the dog was killed and a few drops of pus were found under the graft) these worms were again present. The reason is, I believe, that in these cases there was a thin greenish-yellow fluid bathing the worms; this fluid was only seen when worms were present, and extravasation of this occurred before any plastic lymph was poured out over the line of union.

In carrying out these experiments there was no selection of the dogs; they were operated upon as they were brought to me, some strong and healthy, others unhealthy, mangy, and emaciated; thus the general conditions, apart from the consideration of obstruction, were similar to those which would obtain in man. Those conditions could have been more closely approximated by obstructing the bowel by a previous operation or wounding it by a shot or stab, but I did not feel justified in resorting to a course which would involve much suffering without affording a promise of much further information. In every case the dog was kept well under the influence of chloroform during the operation and all possible care was taken before and after operation to avoid causing pain. It may be interesting to mention that so little did the dogs appear to suffer that in a number of cases they fought the day after being operated upon, either for food or a bitch on heat. Two of the bitches were pregnant at the time of operation (this condition not being discovered until after the abdomen was opened), three became pregnant subsequently to the operation, all five brought forth large, healthy litters, and in no case did any sign of obstruction appear from traction on the bowel due to adhesions. The dogs were all pariahs, running wild in the native city, homeless, mostly starved, and to whom a regular meal was unknown until they were brought to my bungalow. They rapidly grew fat and friendly, and although allowed perfect freedom only two deserted after being operated upon. I desire to express my grateful acknowledgments to the Medical Department of H.H. the Nizam's Government and to Surgeon-Lieutenant-Colonel Lawrie, Residency Surgeon and Principal of the Medical School, for the facilities and resources they so readily placed at my disposal for these and other investigations.

John-street, Adelphi, W.C.

A METHOD OF PRODUCING IMMUNITY AGAINST TUBERCULOUS INFECTION.[1]

BY PETER PATERSON, M.B. GLASG., M.R.C.S. ENG.,
ASSISTANT TO THE REGIUS PROFESSOR OF SURGERY, GLASGOW UNIVERSITY; DISPENSARY SURGEON, GLASGOW ROYAL INFIRMARY.

PREVIOUSLY to undertaking any original investigations in the treatment or prevention of tuberculosis it was necessary to make a number of experiments so as fully to understand the course, terminations, and post-mortem appearances of tuberculous disease when following its usual course after the artificial introduction of tubercle bacilli. To study these phenomena a number of rabbits and guinea-pigs were inoculated by way of the peritoneal cavity, the anterior chamber of the eye, the veins, and the subcutaneous tissues, with the result that the animals died from tuberculosis after the lapse of varying periods—the interval depending on the dose and its mode of administration. During life the chief evidences of the disease were emaciation and fever, the former steadily increasing until death. On post-mortem examination numerous nodules were found in the internal organs, and these nodules when examined under the microscope were found to have the typical structure recognised as that of tubercle.

In addition to the infection of the internal organs those animals which were inoculated in the peritoneal cavity showed a tuberculous peritonitis, and those inoculated in the anterior chamber of the eye a tuberculous pan-ophthalmitis. In these experiments the bacillus of mammalian tubercle was employed and all the inoculations made into mammals were uniformly successful in inducing the disease, but on trying to produce tuberculosis in birds by injections of the same organism the results were invariably negative. In six fowls I injected into the veins doses varying from 1 c.c. to 10 c.c. of a very opaque (almost milky looking) watery suspension of virulent mammalian tubercle, but the birds remained healthy and strong. After periods varying from ten weeks to five months they were killed, when their organs were found to be free from tubercle even after careful microscopic examination. Yet repeated outbreaks of tuberculosis amongst birds are on record, and in these instances the disease has spread very rapidly amongst the birds and could only be eradicated by killing all the infected fowls and thoroughly washing the aviaries with antiseptics. In these cases the only methods of infection could be by inhalation and swallowing, and in both these ways the number of bacilli taken at any one time would be comparatively small, and they would be brought into contact with healthy epithelium either in the lungs or intestine. Yet these few bacilli were able to overcome the resistance offered by this epithelium and gain a nidus in the body, ultimately leading to the death of the infected birds. On the other hand, in the experimental cases above noted, countless numbers of bacilli were injected directly into the blood stream and had therefore no primary resistance to overcome in the form of epithelium, and yet they disappeared from the body of the inoculated animals without leaving any visible trace.

Still, there might be something in the external conditions of these birds which are infected accidentally whilst running about that makes them more liable to infection than those kept in confinement, though the opposite usually holds. To investigate this point five fowls were kept under the same conditions; of these, three had injected 5 c.c. of a watery suspension of virulent mammalian tubercle into the peritoneal cavity, another had the same dose of virulent fowl tubercle introduced into the peritoneal cavity, whilst the fifth was fed on two occasions with food which had 1 c.c. of the same watery suspension of virulent fowl tubercle mixed with it. At the expiration of ten weeks the birds were killed, when those which had been injected with virulent mammalian tubercle bacilli were found free from tuberculosis, whilst the bird which had been inoculated with the virulent fowl tubercle showed numerous tubercles in the viscera, and the one which had been fed with tuberculous food showed tuberculous nodules of the intestine and a tuberculous ulcer of the gizzard.

The question next arises, Are both these varieties pathogenic towards man? As regards the mammalian it is generally recognised that it is virulent to man. That he is susceptible to the bacillus of fowl tubercle is fairly conclusively shown by the following case.

Some time ago when on a visit to the country I was asked by a man who kept poultry if I could give any reason why his birds were dying off, as, so far as he could discover, there was no evident cause. On investigation I found that for a considerable time past occasionally a fowl would become emaciated and weak and ultimately die. As he was poor, and this meant to him a heavy financial loss, he latterly, when he noticed any of his stock ill, killed them and ate their carcasses after cooking by roasting. On killing and examining one of the diseased birds I had no hesitation in pronouncing the disease to be tuberculosis, and advised him to kill his stock and disinfect their houses and feeding dishes thoroughly, and on no account to eat any of the birds. On seeing his family a few months later his wife and daughter were suffering from tuberculous disease, the wife of the intestines and the daughter of the lungs, and from this they both ultimately died. In these cases the infection was derived doubtless from the poultry, either indirectly by inhaling or swallowing the germs as they were blown about in the poultry-house, or more directly by eating the carcasses of the birds, which may have been insufficiently cooked. The man himself I lost sight of. If the ejecta of these patients had been eaten by healthy poultry, the bacilli having been primarily derived from birds would doubtless have infected them, and so the disease would have spread; on the other hand, the experiments above recorded show that the sputum voided from a patient the host of mammalian tubercle would be swallowed with impunity by fowls.

Now, if there are two varieties of tubercle, and man is susceptible to both, a culture obtained from a patient suffering from fowl tubercle should show the characteristic appearances of that organism, cultures of fowl tubercle growing more rapidly and being moister than those of mammalian tubercle.

[1] This article is an abstract of the author's Weber-Parkes Essay which received the second award from the Royal College of Physicians of London.

Digitized by Google

This was actually a strong point in support of the contention that fowl tubercle is only a modification of mammalian tubercle, as hitherto all artificial cultures derived primarily from man have been described as being similar in appearance. Recently I obtained further evidence in favour of a distinction between these bacilli. On opening an abscess and collecting some of the pus to ascertain if it contained tubercle bacilli careful microscopic examination failed to reveal the presence of any germs. A quantity was then injected into the peritoneal cavity of a rabbit. At the end of six weeks, when the animal was killed, tubercles were found scattered over the peritoneum. Some of these were removed with strict aseptic precautions and planted on the surface of glycerine-glucose-agar. No growth was visible for about a week, when a moist white ring appeared spreading out from the implanted nodules. At first I thought I was dealing with a contamination, but I was struck by the similarity of the growth in all the tubes, and on examining the growth more carefully it was found to have all the appearances, both macroscopic and microscopic, of fowl tubercle. I regret that the investigation was not carried further by inoculating birds from the cultures; still, the appearances were nothing like those given by cultures of mammalian tubercle. Only in this one case have I obtained this growth from man; but tuberculosis amongst birds is comparatively rare, and I believe the infection of man with this variety is rarer, otherwise the peculiarities of its cultures would have been frequently observed.

To ascertain if the one variety had any action on the growth of the other variety the following experiments were performed. A number of rabbits had 1 c.c. of a sterilised watery suspension of fowl tubercle bacilli injected into the auricular vein, the bacilli having been killed by one and a half hours' exposure to steam at 100° C. These injections were followed by fever and emaciation, which soon disappeared. 1. One month later ½ c.c. of a very opaque suspension of virulent mammalian tubercle was injected into the peritoneal cavity of several of these animals. To all appearance they remained well, and when killed four and a half months afterwards the only lesion observed was the presence of a number of small pedunculated nodules about the size of lentils adhering to the edge of the liver and the surface of the parietal peritoneum. In no instance did these nodules exceed ten in number. On section they were found to consist of a dense fibrous capsule with calcareous contents embedded in which were a few tubercle bacilli. 2. Others had ½ c.c. of the same suspension of virulent bacilli injected into the subcutaneous tissues. When killed four months later there was a small focus of caseation at the seat of injection, but neither the lymphatic glands nor viscera were infected. 3. Into the auricular vein of others ½ c.c. of the suspension of bacilli was injected. When killed at the end of three months and their viscera submitted to microscopical examination some of the organs taken from a few of the animals presented a few points of irritation as shown by a round-celled infiltration but without any trace of giant cells or caseation; in the remainder of the animals even these points of irritation were absent. During this experiment some of the animals gained as much as half a pound in weight. 4. An injection of 1 c.m. of the suspension of virulent bacilli into the anterior chamber of the eye of another series of rabbits was followed by a tuberculous iritis, but the tubercles soon commenced to diminish in size, so that at the end of five weeks they had completely disappeared in some cases, and almost so in others. On microscopical examination of the latter the nodules were found to consist principally of calcareous salts. 5. One rabbit had all the above injections introduced, and when killed five months after the introduction of the first it was found free from general tuberculosis. This animal gained one pound in weight during the experiment. In the above experiments the effect of introducing the bacterio-proteids of fowl tubercle into rabbits was such as to modify the fluids or tissues of the animals in such a manner that subsequent injections of virulent mammalian tubercle even in large doses were prevented from becoming disseminated throughout the body, but remained localised to the seat of primary inoculation. Further, if the bacilli were in a state of fine suspension and distributed over a large area, as follows an intravenous injection, the tissues were able to destroy them, and the bacterio-proteids thus set free produced the small foci of irritation observed in the viscera. As the proteids were removed the inflammatory points disappeared. When the bacilli were in a coarser state of suspension these injections gave rise to a caseous mass which ultimately became encapsuled and impregnated with calcareous salts, embedded in which one could find tubercle bacilli—the remains of those injected. In other words, injections of virulent mammalian tubercle bacilli into these animals behaved in the same manner as dead tubercle bacilli when these are injected into the same parts.

By injecting the sterilised fowl tubercle directly into the blood stream, as a means to prevent the extension of tuberculous infection, one very obvious disadvantage presents itself—namely, the danger of some of the dead bacilli being deposited in some part of vital importance and setting up an inflammation which might have serious results. This I found actually did occur in several instances where the injections were followed by paraplegia, oscillations of the head, &c. On the other hand, subcutaneous injections produced a caseous mass which on being discharged carried with it a large number of the bacilli which had been introduced, consequently the full advantage of the injections was not obtained. ..... On taking into consideration the immunity shown by fowls against infection by mammalian tubercle, I proceeded to ascertain the effect of their serum when modified by the presence, or action of, the bacterio-proteids of fowl tubercle. Accordingly sterilised suspensions of fowl tubercle were injected into the peritoneal cavity of fowls. The injections were commenced by giving 10 c.c. of a sterilised watery suspension of the bacilli, and at each subsequent injection, these being repeated at intervals of three weeks, the quantity was increased at first by 5 c.c. and latterly by 10 c.c., so that the quantity introduced on the sixth injection was 50 c.c. and the total 165 c.c. After the expiration of the next three weeks the injection of 50 c.c. of the suspension was repeated, and continued to be so every third week. Under this treatment the birds, which during the time occupied by the first three or four injections were emaciated and anæmic, came gradually to be able to withstand the action of the later injections with no apparent detriment to health. I next endeavoured to find if the serum of the fowls so treated had any effect on the growth of tubercle bacilli, both fowl and mammalian. To do this I abstracted some blood from the fowls, having allowed at least a week to intervene between the last injection of sterilised fowl tubercle bacilli and the venesection, and not taking any blood until the sixth injection had been given. Having allowed the serum to separate a quantity of this was drawn into sterilised test-tubes. A number of these were then inoculated with virulent fowl tubercle, others with virulent mammalian tubercle, and then placed in the incubator. After some time there was a distinct growth in the tubes inoculated with the fowl tubercle, but no apparent increase in the number of bacilli in those tubes which had been inoculated with mammalian tubercle bacilli, even although kept for three weeks in the incubator. But here one must be guarded against attributing this want of growth entirely as the result of the previous treatment of the fowls from which the serum was taken, because the fluid serum itself has the power of destroying, within certain limits, any germs which may be introduced into it, and it is possible that the absence of growth was due to this bactericidal property.

Proceeding to try the effect of this serum on healthy rabbits and guinea-pigs I injected 3 c.c. into the subcutaneous tissues of these animals. This was followed in a few hours by a marked rise of temperature, the rise in some cases reaching 3° F. Twenty-four hours afterwards there was a thickening at the seat of injection, and extending for some distance round this point. The injection was repeated once a week until 15 c.c. of serum had been introduced altogether. During this period the animals lost weight, and this emaciation continued to progress for four or five weeks after the cessation of the injections. This loss of weight amounted in one case to 150 grammes, and in one instance, where a dose of 8 c.c. was given, the animal died shortly afterwards. Sections made from the swellings resulting from the injections of serum were found to consist almost entirely of round cells, epithelioid cells, and a few large multinucleated cells. At other points the sections showed small foci having all the appearances of caseation, whilst at others the cells were undergoing a degenerative change, as evidenced by their staining very faintly. Apart from the caseation the above appearances denote the presence of a chronic inflammation only, but the caseation and degeneration reveal the presence of some substance deleterious to the cells of the inoculated animal. That this deleterious property does not belong to the normal serum of fowls was

Digitized by Google

shown by injecting normal serum in similar doses into rabbits. These injections produced a very slight rise of temperature and very little swelling, but nothing similar to the degenerative changes above described.

In the foregoing experiments the caseation could not be due to the highly improbable event of any of the dead bacilli injected into the fowl having got into the circulation and escaping with the blood withdrawn, then reinjected with the serum into the rabbits and guinea-pigs, because it has been shown that isolated bacilli do not produce caseation. This result, therefore, must be due to something dissolved in the blood of the fowls, or else their serum is so modified that it is able to produce this change, and yet the birds themselves are to all appearances healthy. I now proceeded to try the effects of the serum on tuberculous animals. For this purpose a number of rabbits were inoculated by the anterior chamber of the eye with virulent mammalian tubercle bacilli. These injections were followed by intense iritis, the formation of yellowish spots on the iris, and slight opacity of the cornea. A fortnight later 2 c.c. of the prepared serum were injected subcutaneously, and this dose was repeated weekly for four weeks. At the end of this period the affected eyes were acutely inflamed, the iris in some cases looking like granulation tissue. After the injections ceased this condition of intense inflammation improved, and a month later the pupils were distinct and the redness had disappeared from the iris, scattered over which a few yellowish specks could be seen. For five or six weeks the eyes remained in this condition, there being no apparent increase in size or number of the yellowish specks situated on the iris. The injections of serum were then recommenced, the dose being 2 c.c., and repeated weekly for three weeks. As a result of this the nodules on the iris increased in size, but there was no development of any fresh foci. Six months from the injection of the mammalian tubercle into the eyes, the animals were killed. On examination the bodies were found to be well nourished, and, excepting the tubercles in the eyes, the animals were free from tuberculous infection.

The results of these injections show that the serum when injected into a tuberculous animal tends to limit the extension of tuberculosis to parts other than those primarily involved, as evidenced by the absence of any tuberculous disease in the internal organs. Even in parts where the disease has become established before the serum is introduced it has a pernicious influence, as in none of the infected eyes did the tubercles exceed seven in number, although 2 c.m. of an opaque watery suspension of virulent mammalian tubercle bacilli had been injected and six months elapsed between the primary inoculation and the death by killing of the animals. The intense inflammation in the eyes during the period of the first series of injections of the serum, followed by a period of quiescence of the tuberculosis after their cessation, and again the increase in the size of the tubercles during the second series of injections, leads one to the opinion that the serum when injected into an animal suffering from tuberculous disease aggravates the affection so long as the injections are continued; but when time has been given for this serum to influence the fluids of the body these fluids are able to a certain extent to prevent any further extension of the disease. If this be so then it would be possible to render susceptible animals immune to the action of the tubercle bacillus by injecting a quantity of this prepared serum and allowing some time to elapse before exposing the animals to tuberculous infection. Hence I endeavoured to make guinea-pigs and rabbits immune to the action of the mammalian tubercle bacillus. The animals had injected subcutaneously doses of 2 c.c. of the prepared serum, the dose being repeated every third day until five injections had been given and they had received a total of 10 c.c. of serum. These injections were followed by the usual rise of temperature, swellings, and emaciation, but after their administration had been stopped these symptoms gradually disappeared. One month from the date of the last injection of the serum virulent mammalian tubercle bacilli in watery suspension were injected into the anterior chamber of the eye of a number of rabbits. This injection gave rise to an acute iritis accompanied by opacity of the cornea. These symptoms continued for a few weeks and then gradually diminished, so that by the end of the sixth week they had completely disappeared and no trace of tubercle could be found in any part of the body on making a post-mortem examination. Two months later—that is, three months from the date of the last injection of serum—1 c.c. of an opaque watery suspension of virulent mammalian tubercle was injected into the peritoneal cavity of a number of guinea-pigs. After this injection the animals appeared to remain in their usual health and were all killed in from two to two and a half months after the introduction of the mammalian tubercle. During this period there was no emaciation, as shown by the absence of loss of weight. On post-mortem examination the only evidences of any injection of irritant matter having been made into the peritoneal cavity was in one case an adhesion of the liver to the diaphragm and in another the presence of three small nodules, about 0·5 mm. in diameter, in the edge of the omentum, which otherwise was normal. All the viscera were perfectly healthy and free from any trace of tubercle even on microscopical examination. Sections of the nodules above mentioned showed that they consisted of a dense, fibrous capsule enclosing amorphous matter, lime salts, and fat globules of various sizes. In none of the sections was there any evidence of an active process, and careful examination failed to reveal the presence of tubercle bacilli. The existence of these nodules may have had nothing to do with the injection of the tubercle bacilli; but from their structure it is highly probable that they were the result of the inoculation, though the bacilli had disappeared. Five months after the injection of the serum a number of the remaining animals had virulent mammalian tubercle injected into the subcutaneous tissues, whilst in others the same organism was introduced into the peritoneal cavity. The subcutaneous injections acted in the same manner as injections of dead bacilli into the same situations—that is to say, a caseous mass formed which was discharged without giving rise to any infection of lymphatic glands or viscera. The injections into the peritoneal cavity disappeared without leaving a trace.

How long this acquired immunity will last in animals it is impossible at present to say definitely, but the results of the last set of experiments recorded above show that it is effectual for at least five months. Having obtained the serum of fowls in such a condition that its injection into such susceptible animals as guinea-pigs and rabbits conferred immunity against the invasion of large numbers of mammalian tubercle in a virulent form I proceeded to try its effects when injected into a healthy man. With this object I injected 2 c.c. of the serum into my thigh. This soon gave rise to pain, which extended for some inches round the needle puncture. Eight hours afterwards the part was slightly swollen and the skin over it was distinctly red. This pain, redness, and swelling lasted for four days, and during this period the femoral glands became enlarged and painful. At the end of this time the above symptoms (with the exception of the enlargement of the glands) gradually disappeared; but two days later—that is, seven days after the injection—pain was felt in the thigh about four inches from the point of injection, the parts immediately surrounding this point being quite free from any tenderness. The skin over the painful part was inflamed. These symptoms continued for three days longer and then disappeared, and at the same time the enlarged femoral glands commenced to diminish in size. During this period the temperature never exceeded 99·4° F. Two weeks after the first injection 5 c.c. of serum were injected into the other thigh. This gave rise in two hours to severe pain at the seat of injection and extending for about three inches round this point. There was also slight swelling of the part. Nine hours after the injection the skin over the part was distinctly red. The temperature was 99·2° and the pulse was 100 per minute. Nine hours later the part was much swollen, the swelling being defined by a red, raised margin. The inflamed part was very tender to pressure. The temperature was 100° and the pulse was 104 per minute. Ten hours later—that is, thirty hours after the introduction of the serum—the skin was very red, the redness extending almost from the knee to the groin and nearly completely round the limb. The glands in the groin were enlarged and painful. The temperature was 100 2° and the pulse was 104 per minute. A few (four) hours later the temperature rose to 100 4°, and there were headache and profuse perspiration. These latter symptoms continued for about eight hours, when they disappeared and the temperature and pulse fell to normal. About the same time the blush over the thigh resolved except from the edges, but the skin was still very much thickened over the affected area. Three days after the injection the limb was almost well, there being only slight thickening round the point of injection. During the whole of this period the femoral glands remained enlarged though

Digitized by Google

painless, and this enlarged condition persisted for six weeks from the date of injection. From the degree of reaction which followed the second injection I believe that the increase from 2 c.c. to 5 c.c was too great, and that a more gradual rise in the quantity introduced would be followed by less disturbance.

In man we cannot push the experiment to the test of injecting into his body virulent mammalian tubercle bacilli after the injection of the serum, but we are justified in concluding that if such susceptible animals as guinea-pigs and rabbits are rendered immune by this method against the invasion of large doses of the virulent bacillus introduced into their bodies, man, who is much less susceptible, can in the same manner be rendered immune against the invasion of the few bacilli which may at any one time attack him. I believe this condition of immunity can be attained in man by commencing with an injection of 2 c.c. of the serum, and increasing each administration by 1 c.c until its influence on the body is shown by a distinct rise of temperature. At least a week should intervene between each injection.

The length of time this immunity so acquired will last can only be definitely ascertained by observations in a large number of cases and extending over a number of years; but even if the immunity should be found to diminish or disappear after the lapse of a number of years this does not reduce the value of the serum as a prophylactic, because the injections can be repeated at stated intervals and the immunity re-established. So far as my observations go I am unable to claim any curative effects from the use of the serum in patients suffering from tuberculous disease, but I hold, and that most emphatically, that when injected into susceptible bodies it confers on these an immunity against the invasion of the bacillus of mammalian tubercle. Especially do I recommend these injections to be given to persons who have a tuberculous tendency and to those who have a history of tuberculous disease amongst their relatives. By this means it is possible to diminish, if not altogether to eradicate, tuberculous affections from the race, and as such do I venture to bring it before the notice of the profession.

Glasgow.

TWO CASES OF PERFORATED GASTRIC ULCER TREATED BY OPERATION.[1]

BY A. R. ANDERSON, F.R.C.S. ENG.,
SURGEON TO THE GENERAL HOSPITAL, NOTTINGHAM.

CASE 1.—The patient, a girl aged sixteen years, was seen in consultation with Dr. Hunter on Nov. 26th, 1895, and the case was diagnosed as one of perforated gastric ulcer. As her surroundings were such as to prevent operation at home I advised her removal to the General Hospital, and she was admitted at 2.30 P.M., about an hour after my visit. The history obtained was as follows. She had for some years been rather anæmic. For three weeks she had been troubled with symptoms of indigestion, for which she had taken some medicine, but which had not been severe enough to induce her to seek medical aid. Her appetite had been extremely good; she always felt hungry and ready to eat anything. In fact, it had for some time been abnormal. The actual attack occurred at 6.30 P.M. on Nov. 25th, the day before I saw her, about half an hour after tea. At this meal she had eaten a small pork pie, some fried bacon, and several helpings of bread and butter and marmalade, and had drunk two cups of tea. She was seized with intense pain in the abdomen above the navel, which doubled her up and which became so severe that she fainted. With difficulty she subsequently got to bed, and passed a sleepless night in great suffering, trying various remedies to relieve the pain. Thirst seemed to have troubled her greatly. During the night she told us that she drank two pints of milk, ten glasses of water, and two syphons of soda water, and in addition to this in the way of medicine, some "Mother Seigel's Syrup," a dose of salts, some ginger and "gripe mixture." In the morning Dr. Hunter was sent for, who at once recognised what had happened, and she reached the hospital as stated at 2.30 P.M. At this time she was suffering from shock and symptoms of commencing general peritonitis. There was great pain and tenderness all over the abdomen which was uniformly but slightly distended. The muscles were perfectly rigid and immobile during respiration. The liver dulness was diminished and the rest of the abdomen was hyper-resonant to gentle percussion. Her face was pale and the expression anxious; the pulse was 130, the respirations were 28, and the temperature was normal. There had been no vomiting. She was aware that the repeated draughts of fluid taken during the night had increased the pain. I operated at 3.30 P.M., an hour after her admission and twenty-one hours after the onset of the symptoms. An incision five inches long was made in the mid-line chiefly above the umbilicus. On opening the abdomen it was found to be full of an opaque fluid in which particles of food were floating. The bulk of this having been removed the stomach was then examined. Nothing was to be seen on that part of it within easy reach, but some thickish fluid containing small solid particles was observed coming down from high up under the left lobe of the liver, and following this up a perforation was found on the anterior surface of the stomach close to its cardiac end, which would admit the end of the finger. By lifting up the left lobe of the liver and the costal cartilages and drawing the stomach downwards and backwards the hole was brought sufficiently into view to enable the sutures to be passed. The material used was silk. After its closure the abdomen was flushed out with boiled water and sponges were finally used for the removal of any fluid or particles that remained. The abdominal incision was completely closed. The operation occupied one hour and five minutes from the commencement of the anæsthetic. I am much indebted to Dr. Sedgwick, one of our house surgeons, for the full and accurate record which he took of this case. The following is a *résumé* of the leading features of the subsequent history. For nine days after the operation the patient progressed without an unfavourable symptom of any kind. The temperature never rose above 100° F., and only reached this point on one occasion. The pulse rate dropped to between 80 and 90 and the abdominal symptoms disappeared. For the first four days the feeding was entirely rectal; after this peptonised milk in small but increasing doses was given by the mouth. The bowels acted regularly in response to simple enemata. The abdominal wound at the end of this period had practically healed and all the sutures had been removed. The patient was repeatedly asking for solid food, and, indeed, seemed convalescent. On the evening of the ninth day the temperature rose to 101°, and on visiting her next morning I found her not quite so well. The temperature had fallen to normal, but she complained of some malaise, headache, and pain in the right shoulder. The pulse-rate had risen to 100. Nothing fresh was discovered on examination of the abdomen. On Dec. 9th (two days later) the patient was in much the same state, the temperature rising to 101° at night and falling to normal in the morning. There was a little swelling at the upper part of the wound with redness round the track of one of the sutures, and a small quantity of pus was let out from a subcutaneous abscess, evidently in connexion with the stitch holes. On the 16th there was slight improvement following on this, but it was not maintained. The temperature during the week varied between 99° and 101·5°, and now suddenly jumped up to 104.° There had been no shivering and no evidence of peritonitis, local or general; the abdomen was flat, and palpation was painless. The only complaint was of headache and pain in the right shoulder over its convexity. These symptoms had persisted during the week. There was no swelling of the shoulder, and its movements were free and painless. In the last twenty-four hours a slight cough had developed and she vomited for the first time during her illness. Dr. Handford saw the patient at my request and carefully examined the liver region and the bases of both lungs, but he could detect nothing abnormal. On the 19th the temperature was still high and fluctuating between 101° and 103°, and in addition to the symptoms mentioned above complaint was now made of pain in the epigastrium. In the absence of Dr. Handford, Dr. W. B. Ransom kindly examined her chest for me, but was unable to discover any signs of fluid at the back of the chest or in front. The liver dulness was normal, and there was no visceral displacement. Thinking it probable that pus existed I decided to operate again, and did so on the following morning (the 20th). The patient was anæsthetised,

[1] A paper read at a meeting of the Nottingham Medico-Chirurgical Society on Feb. 3rd, 1897.

Digitized by Google

and an incision four inches long was made in the right linea semilunaris beginning at the costal margin. This exposed the anterior edge of the right lobe of the liver. Nothing was found here either between it and the diaphragm or on its under surface. There were two or three stones felt in the gall-bladder, which was otherwise normal. The incision was then closed and the original wound was opened up and the left lobe examined and also the stomach in the region of the ulcer. There was nothing wrong here, and it was evident that there had been no leakage. This wound was then closed. The shock was slight and soon recovered from. Three days after, on the 23rd, she was still complaining of persistent headache and right shoulder pain, and some pain all over the chest. Cough had now become a prominent symptom and was especially troublesome at night. There was a scanty frothy expectoration. Abdominal examination showed nothing fresh. The wounds were healing without suppuration. On the 30th her condition was distinctly worse. There was more cough and dyspnœa and some drowsiness. The temperature varied from 102° to 103° at night, being lower in the morning. She complained persistently of pain round the right shoulder and of headache. The respirations were 40 and the pulse was 124. The chest was again examined by Dr. Handford, who found some moist sounds and slight crepitations over the upper part, and suggested the possibility of acute phthisis—two brothers had died from the disease,—but failed, as I had done, to detect the presence of fluid anywhere. The sutures were removed, the wounds having healed. There was no evidence of peritonitis. From this time until her death, which occurred five days later, the pulmonary symptoms increased, the dyspnœa becoming more urgent; and on Jan. 2nd, 1896, distinct signs of double broncho-pneumonia were found, and oxygen was administered with strychnia, digitalis, and stimulants. Treatment proved to be of no avail, and she gradually sank and died on Jan. 4th, five weeks and four days after the date of perforation.

Necropsy.—On opening the abdomen there were no signs of peritonitis and no fluid in the peritoneal cavity. The stomach in the region of the ulcer was slightly adherent to the under surface of the left lobe of the liver. The adhesions were easily separated and the stomach was removed. The perforation was situated on the anterior wall close to its termination in the œsophagus. It was soundly healed. The gall-bladder was distended and contained five small calculi. No pus was found on examination of the liver *in situ*, but on removing it an abscess was found between the diaphragm and the posterior part of the right lobe, containing about six ounces of thick pus. The area of suppuration was limited by firm adhesions between the liver and diaphragm, which confined it almost to the angle between the diaphragm and the posterior border of the right lobe. On cutting into the liver a number of scattered abscesses were found, varying in size from a nut to that of a pea. Both lungs were affected with broncho-pneumonia. The other organs were healthy. There was no fluid in the pleuræ.

CASE 2.—A young woman, aged nineteen years, was admitted into the General Hospital on Dec. 16th, 1896, with the following history. She was working as a machinist, but had not been able to follow her occupation recently on account of ill health. For some time she had been suffering from dyspeptic symptoms, and was thought to have a gastric ulcer, for which she had been treated in the out-patient department. Her diet had been regulated and a mixture containing bismuth and soda ordered. She had vomited on many occasions after food, but there had been no hæmatemesis or melæna. She was anæmic. On the morning of Dec. 15th, the day before admission, she took a breakfast consisting of a pint of bread and milk at 8 A.M., having had the same for supper the night before. At 10.30 A.M., whilst washing her hands after cleaning the bedroom, the patient was taken suddenly with violent pain in the abdomen, which almost made her faint, and was with difficulty got upstairs, where vomiting occurred. She was seen by Dr. Blurton at 4.30 that afternoon and again the next morning, and was admitted into the hospital during the afternoon. Only a few teaspoonfuls of milk and soda water had been taken between the time of the attack and her admission. On examination the patient was found to be suffering from a moderate degree of shock, her expression was anxious, the pulse was 130, the respirations were 24, and the temperature was 99·4° F. Severe abdominal pain was complained of. The abdomen was rigid, scarcely moving on respiration, the left rectus being especially tense. There was marked tenderness above the umbilicus, but no distension. The liver dulness began at the sixth rib in the nipple line and extended downwards for 1½ in. The heart and lungs were normal. The patient being anæsthetised, I operated at 5.30 P.M., an hour after admission, and thirty-two hours after the onset of the symptoms. An incision was made in the mid-line extending downwards from just below the xiphoid cartilage. On opening the peritoneal cavity some odourless gas escaped, and the peritoneal covering of the transverse colon and the omentum which presented was found to be markedly injected. The small intestines were affected to a less degree. There was a small amount of turbid fluid, but nothing that could be recognised as stomach contents. At first no lesion could be discovered, but on enlarging the wound in an upward direction and drawing down the stomach a perforation was found on the anterior surface, close to the cardiac end, very much in the same situation as in the first case. It was quite small, of a size that would admit a probe, and surrounded by a layer of lymph. The stomach wall around it for ¼ in. was distinctly thinned and showed up the outline of the ulcer. It was excised, leaving an opening in the stomach 1½ in. long and ¾ in. broad. This was closed by means of Lembert's sutures, silk being the material used. The abdomen was then flushed out by pouring in boiled water, and finally the whole region between the diaphragm and the liver was douched and then wiped clean with a flat sponge. The abdomen was closed in the usual way, the operation lasting forty-five minutes. The subsequent progress of this case was very satisfactory. For three days the patient was fed by enemata and then began to take food by the mouth in gradually increasing quantities. She is now well.

Remarks.—I have related the first case in some detail as it affords a good example of sub-phrenic abscess and of the difficulties attending its diagnosis, especially as regards the localisation of the pus. The prognosis in cases of perforated gastric ulcer varies considerably according to the time which has elapsed between perforation and operation, the size of the opening, and the amount and kind of stomach contents extravasated. In respect of all these particulars this case must be regarded as an unfavourable one. The operation was done after a lapse of twenty-one hours. The hole was large, and an extraordinary quantity of stomach material (corresponding with the amount taken by the mouth) was found in all parts of the abdomen, samples of pork-pie, bacon, bread, marmalade, tea, and milk being visibly represented. I removed pieces of food from both loins and from Douglas's pouch, while the small intestines were floating in pints of turbid milky fluid. As far as this detail went the case could hardly have been worse; yet there was no subsequent peritonitis, and she would undoubtedly have recovered but for the localised suppuration under the diaphragm. No doubt the contents of the stomach are much less dangerous than are those of the intestine when they escape into the peritoneum. All went well with this patient until the ninth day, when unfavourable features began to show themselves. The symptoms presented before the later stages in which the case became complicated with general sepsis are worth bearing in mind. They were pain round the right shoulder, headache, and general malaise, a rise in the temperature and pulse rate, and subsequently pain in the epigastrium. The pain round the shoulder was so persistent and formed so marked a feature that I should in future attach a good deal of importance to it. The question of sub-phrenic abscess was discussed, but I never succeeded in locating it, and my colleagues, Dr. Handford and Dr. Ransom, who repeatedly examined the patient, were unable to discover any physical signs by which its presence could be positively determined. I believe there is no spot in the body where the detection of pus is more difficult than at the back of the right lobe of the liver. This is fortunately an unusual situation for it to occur. After gastric perforation sub-phrenic abscess has been far more commonly found under the left arch of the diaphragm and is attended with signs of localised peritonitis in the epigastric and left hypochondriac regions. But the difficult question remained in this case, Was there any collection of pus, and if so where?

The second operation demonstrated, as I thought, the absence of pus under the diaphragm, as none was found anteriorly between either lobe of the liver and the muscle. This case teaches the important lesson that matter may form and become encapsuled about the posterior border of the liver without any evidence

Digitized by Google

of its existence being discoverable by a reasonable exploration from the front. If the diagnosis were made the best course to pursue in treating such a case would be to resect a couple of ribs posteriorly, incise the diaphragm, and evacuate the pus through the pleura. This route should be chosen for two reasons—because it is the nearest by which it could be reached and also because, although the passage of this highly septic material through the pleura would not be free from risk, such risk would be very much less than conduction through the peritoneal cavity, the only other possible method of exit. If unrelieved by operation these abscesses prove very fatal from septicæmia and often infect the pleura and lung of the same side. They sometimes occur as the result of a minute perforation of the stomach which has been closed by adhesions to neighbouring organs and either has not been diagnosed or is accompanied by symptoms not severe enough to make the need for immediate operation clear. In these cases the few drops of stomach contents which escape are sufficient to start the septic process which results in the formation of an abscess in an inaccessible position which soon endangers life. This furnishes an additional reason for the need of immediate operation if the diagnosis of perforation can be made. Such abscesses may occur between the diaphragm and the left lobe of the liver, between the stomach and the liver, between the stomach and the spleen,[2] and lastly between the diaphragm and the right lobe of the liver. In this connexion it is well to remember that in a very large percentage of cases of perforating ulcer the lesion has been found on the anterior surface of the stomach.

Prevention of this unfortunate complication is better than cure, and sub-phrenic abscess can be largely guarded against by the technique observed during the performance of an operation for perforated gastric ulcer. The convex surface of the liver and the pouch that exists above its posterior attachment is the one spot in the abdomen which is likely to be overlooked in the cleansing process if the operator has not this region in mind, and it is a part to which the experience of these two cases has taught me especial attention should be given. In the second case after the toilet of the abdominal cavity had been completed I washed out several ounces of escaped stomach contents from above the liver, which would almost certainly have caused suppuration if left. In both cases the same plan of cleansing was followed, and the results obtained would induce me to repeat this method. The lips of the wound being held apart and lifted up, large quantities of boiled water were poured into the abdomen out of jugs, the size of those used in bedrooms, until it returned clear. This is much preferable to the douche as the volume of water flushes out the cavity very effectually, and it also effects a considerable saving in time. Afterwards the remaining fluid was removed with sponges and wiping was resorted to in any suspicious situations. In cleansing the sub-phrenic space a rubber tube attached to a douche was pushed well to the back of the liver on either side of the suspensory ligament, and by raising the costal margins and depressing the liver, the whole of the convex surface was in this way cleansed. After the water returned clear a flat sponge was introduced down to its posterior attachments and the space wiped out. In the first case the region in question was not cleaned out so thoroughly as this; had this plan been adopted no doubt a successful result would have been obtained.

With respect to the incision it was the same in both cases, a median one, extending from just below the xiphoid cartilage to the umbilicus, or a little below it. This should be sufficient for the closure of a gastric ulcer wherever situated, without any side incisions or cross cuts. Through this opening the whole of the interior of the abdomen can be reached and the various localities where food is likely to collect—the loins, Douglas's pouch, &c.—can be effectually washed and afterwards sponged out. I found no difficulty in passing the hand into the pelvis and wiping its floor with a sponge. In both cases the wound was completely closed and no drainage employed. In the second case the ulcer was excised.[3] The specimen showed well its clean punched-out appearance on the mucous surface and the small round perforation through the peritoneal coat. The question as to whether excision is advisable is still an open one. Some writers deprecate it on account of (1) the additional time consumed; (2) the additional hæmorrhage occasioned; (3) the increase of shock to the patient by converting a small hole into a large gap, requiring a great number of sutures for its closure; (4) the risk of a considerable addition to the escape of the gastric contents; and (5) the difficulty in closure owing to protrusion of the mucous coat. These objections in many cases would be real enough to make the operator decide to give closure the preference over excision. In Case 2 the local appearances indicated clearly that the ulcer was a small and deep one, but even this left on its removal a wound in the stomach wall one and a half inches long by three-quarters of an inch broad, and required fourteen sutures for its closure. I have now the satisfaction, however, of knowing that the woman's disease is cured, that the previously existing symptoms have disappeared, that her digestion is normal, and that she has, I believe, been completely restored to health.

Nottingham.

[2] An interesting specimen of abscess in this situation was shown to the meeting by Mr. W. J. Stephens. The patient, a middle-aged woman, died from what was thought to be a malignant growth under the liver. She was only seen by Mr. Stephens shortly before death, and no clear history could be obtained. Post mortem an ulcer of the stomach was found which had leaked through a minute opening and occasioned an abscess containing nearly a pint of matter, lying in the left hypochondriac region between the stomach and the spleen. There was no general peritonitis.

[3] Both the specimen and the patient were exhibited at the meeting.

A CASE OF

STRANGULATION OF THE ILEUM BY PASSAGE THROUGH A CONGENITAL MESENTERIC HOLE; OPERATION; RECOVERY.[1]

BY J. STANLEY KELLETT SMITH, F.R.C.S. ENG.

A GIRL, aged fifteen years, was seized, while walking in the street on the afternoon of June 23rd, 1897, with violent abdominal pains, quickly followed by persistent vomiting. Mr. Bassett Jones, of Aberystwith, who saw the girl the next morning, reported on her condition then as follows: "The patient complained of severe pain referred to the umbilical region; the pain was continuous, but accompanied with paroxysmal exacerbations about every ten minutes, during which the patient suffered great agony. The tongue was furred. The pulse was 90, sharp and small; the respirations were 20; and the temperature was 98·2°F. The abdomen was flaccid and flat, with the walls moving on respiration; there was no local swelling to be seen. It was resonant on percussion, but not tympanitic; there was a small area of dulness in the right iliac fossa, over which there was some tenderness on pressure. Palpation revealed nothing, except a sense of resistance over the above-mentioned area of dulness. There was no passage of flatus or fæces. Vomiting was frequent and of a bilious character; the act was not preceded by much nausea and the stomach emptied itself without apparent effort. Rectal examination revealed only the presence of small scybala." The lower bowel was emptied by enemata and everything that could be suggested in the way of palliative treatment was tried, but without relief to the symptoms. I saw the patient in consultation on June 27th, four days after the onset of the illness. Intestinal obstruction had remained complete, and she was then in a state of great exhaustion. The pulse was 140 and of very unpromising character. The respirations were 32. The abdomen was tympanitic, excepting a small patch of dulness in the right iliac region, and over this patch any pressure upon palpation was strongly resented by the muscles of the abdominal wall. When I saw her vomiting had just taken place, the ejected matter consisting of diluted bile with particles of curd of the milk which had been given in small quantity as food. There was no suspicion of fæcal odour. Operation was advised and immediately carried out. The abdomen was opened from the umbilicus to the pubes. Coils of distended and congested small intestine bulged through the wound and the escape of these was encouraged until the disposition of the mesentery could be comfortably made out. The gut was then carefully drawn from the abdominal cavity, proceeding always downwards, until the lower part of the ileum was reached, tender manipulation being here necessary owing to

[1] A paper read before the Liverpool Medical Institution on Oct. 21st 1897.

Digitized by Google

the greatly increased congestion of the bowel. The cause of mischief was found in the shape of a hole in the lower part of the mesentery, pyriform in shape, measuring some two and a half inches by two inches, with its larger end close to the mesenteric attachment of a small loop of bowel, which, taking its upper and lower limits as fixed points, had swung itself through the hole and thus become strangulated. The parts were judged capable of recovery and so were restored to normal position, recurrence of the accident being guarded against by closure of the aperture. The exposed intestines were then washed with weak perchloride solution and replaced in the abdominal cavity with some difficulty, but without the necessity of puncture for gas drainage. The total time of operation occupied thirty-five minutes. Recovery was uninterrupted. Flatus passed on the day following the operation, and the bowels were voluntarily moved on the fourth and subsequent days.

Remarks.—Holes may occur in the mesentery as the result of disease, of injury, or of congenital malformation. The absence of any sign of previous disease or injury and the negative history thereof, the smooth thickened margin of the aperture, its size and the regularity of its outline, and especially its situation in the lower part of the mesentery, at the spot where such developmental deficiencies most frequently occur, lead me to regard this case as a typical example of a congenital mesenteric foramen.

Liverpool.

ATONIC APHONIA.

BY ALEXANDER WALLACE, M.D. OXON., M.R.C.P LOND.,
SENIOR PHYSICIAN TO THE ESSEX AND COLCHESTER HOSPITAL.

AFTER reading Dr. Bastian's clinical lecture on Hysterical Mutism and Other Functional Speech Defects, published in THE LANCET of Sept. 25th, 1897, p. 775, it struck me that the following case might be interesting as presenting some points of difference to the cases mentioned by him in his paper.

A man, aged thirty-seven years, married, the parent of two children, the youngest of whom was five years old, came to consult me on July 7th, 1897. Eighteen weeks before he had suddenly lost his speech, never having been dumb before. His hearing and other senses were perfect, and his general health, he said, was good, but he had never been strong. His parents had both died from old age. About a week after the seizure he, by the wish of his medical attendant, went to a London hospital, where, according to his account, he was an hour under examination. His larynx was examined externally and by the laryngoscope, and he was somewhat roughly treated, he said, to make him cry out, but to no purpose, and he had remained in the same dumb state since. He was a rather spare, short man, of nervous habit, and somewhat depressed. His wife accompanied him. He wrote in my presence statements regarding himself coherently and accurately; attempting to speak, the lips and tongue movements were correctly made as if speaking, but no sound issued, not even a whisper; this his wife stated was his then normal condition. He complained of some languor and feebleness, with restlessness at night. There was no cough; his appetite was bad, but the bowels were regular and the urine was acid. His memory was good. Sometimes he felt a sudden fluttering at the præcordia with headache. Sensation was unimpaired. Locomotion was not so good as before. "He knows exactly what he wants to say, and frames the words with his lips, but no sound comes." The features were straight and the tongue was not deflected; no trace of any prior cerebral attack could be detected. The pulse was irritable, 90, of good volume, but rather tense. Examination of the neck and external larynx revealed nothing but some old superficial cicatrices. The heart sounds were normal, but rather weak; cardiac dulness was normal. The liver, spleen, and abdomen were normal. The battery had, he told me, been applied to him both at the hospital in London and afterwards by his medical attendant both externally to the larynx and internally, but without any result. The case seemed to me to be unusual because: (1) there was no evidence or history of any cerebral implication; (2) there was not the slightest whisper, such as we hear in hysterical mutism; (3) the mouth and lips were correctly acting as if articulating, yet no sound issued; and (4) his written answers and his written sentences were correctly given and spelt. On further inquiry I elicited that twice since the attack during the first month he had pronounced the names of people distinctly and correctly, but felt weak and vertiginous afterwards, with pain at the præcordia and great pallor; that he was a great walker, doing generally ten miles a day; that he was restless and excitable, brandishing his arms much; and that he smoked six pipes a day and indulged in coitus three times a week. I thought I saw daylight in these faulty habits. I cut down the coitus to once a fortnight, the pipes to two per day, and a bicycle was to be used in moderation instead of walking ten miles a day. I gave him an acid mixture with five minims of solution of strychnia and one and a half grains of quinine three times a day. To my surprise on July 16th the patient came to me to say that on the 14th he spoke audibly, "I feel better," and that he has since spoken a little each day in the evening; he spoke to me that day clearly; in a low, distinct voice he said that he slept better. The pulse was 80 and soft. I saw him again on July 29th; he had quite recovered and had had no return of the mutism. It seems to me that "atonic mutism" is the right description of what I suppose is a somewhat unusual but happily an easily recoverable form. I have recently heard that he remains quite well.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PERMANGANATE OF POTASSIUM AND OPIUM POISONING.

BY REGINALD NITCH-SMITH, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE SENIOR HOUSE PHYSICIAN AND CHLOROFORMIST, WESTMINSTER HOSPITAL.

THE following case of accidental opium poisoning with successful treatment occurred whilst I was in charge of the casualty department of Westminster Hospital.

A male adult, aged thirty-five years, well nourished, gave on his recovery the following history: "At four o'clock this morning I took two tablespoonfuls of laudanum in mistake for black draught, after which I went to bed, and on being called at seven I thought something must be wrong as I felt so drowsy. I examined the bottle and found I had made a mistake. I then took the proper black draught, got up, and went for a walk. On passing the hospital I felt so very sleepy that I thought it best to come in for treatment." When I saw him, four hours after he had taken the opium, the patient was asleep on one of the seats in the surgery. I immediately roused him, gave him some strong coffee and a hypodermic injection of caffeine, three grains. Two porters were instructed to walk the patient about. His pupils at the time were contracted and failed to respond to light; the mouth was dry and the tongue coated; the skin was cold and clammy. The pulse was 108 and feeble, respiration was somewhat laboured, and the muscles were relaxed. He could only just be roused by loud shouting. Two more caffeine injections were administered with no beneficial result. I now decided to try permanganate of potash, which I gave in the form of the liquor, four drachms. As a result there was slight improvement. Soon after I again gave him four drachms, thus making in all one ounce, = 4·8 gr. Fifteen minutes later the patient vomited a large quantity of black fluid. From then his recovery was rapid and complete. He was, as is usual in these cases, admitted into one of the medical wards and detained for forty-eight hours, my instructions to the nurse being to watch the patient closely and to administer nourishment every three hours. On testing the urine it was found to be normal. There was no meconic acid. It will be seen that the draught taken by mistake contained 33 grs. of opium or 3·3 grs. of morphine.

Dr. William Moor, of New York, ascertained that one grain of permanganate of potash oxidises one grain of morphine. With such undisputed evidence before us it is surprising that such a reliable and easily attainable antidote

Digitized by Google

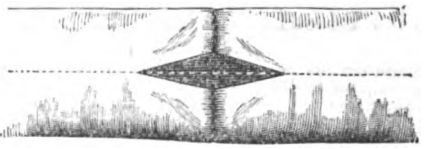
for opium poisoning does not find a prominent place in text-books on poisons and their treatment. The important point in this case is that the permanganate of potash had its desired effect even after five hours had elapsed from the time of taking the poison.

Bessborough-gardens, S.W.

PUERPERAL ERYTHEMA.

BY JOHN JOSEPH STACK, L.R.C.S. IREL., L.R.C.P. EDIN.

ON Aug. 22nd I attended a woman, aged thirty years, who was in her second confinement and was delivered naturally of a healthy male child. Her recovery was uninterrupted for seven days, when she unfortunately used the commode with her bare feet resting on cold oilcloth, and next day (Aug. 29th) complained of a severe headache and thirst, and vomited slightly. The patient's pulse was 120, soft and compressible, and her temperature 103° F. The uterus was syringed out and twenty grains of quinine were given in the form of pills. Immediately after drinking some iced water she was seized with an ague-like rigor which lasted twenty minutes and was followed by profuse sweating. The patient's temperature increased to 105°, and she was hysterical, her pupils being widely dilated and her face flushed. I removed some clots from the patulous os uteri, and injected hypodermically one-fiftieth of a grain of ergotinine citrate. In about half an hour the temperature fell to 100°, her pupils contracted considerably and the headache passed off, but she still looked very haggard and worn. On Aug 30th she felt better; the temperature was 101·2° and the pulse 104. The patient's face and hands were quite red, and there was also a scarlet rash over the breasts. By night time the temperature fell to 99°. On Sept. 1st she passed some clots of blood per vaginam and complained of headache and throbbing on the top of the head. The rash was well out on the trunk. The temperature was 99° in the morning and 99 5° in the evening. On Sept. 2nd she was comfortable and cheerful, but there was an offensive discharge and the uterus was again washed out. The rash was well developed mostly on the trunk and legs. The temperature was 100·4° in the morning and 100° in the evening. On Sept. 3rd the temperature was 100·4°. The rash was well out and extended to the arms and hands, the fingers being swollen and covered by red elevated patches. The uterus was again washed out. On Sept. 4th the temperature was 100·4°. The rash was then disappearing. The urine contained no albumin or sugar. The face appeared puffy; the right breast was hard and painful. On Sept. 5th the rash was completely gone. An abscess was opened in the right breast, which gave trouble for about a week subsequently. The patient ultimately made a complete recovery. There was no desquamation after the rash, the throat was not at all affected, and there was no possible history of scarlatinal contact.



New Cross, S.E.

"A METHOD OF UNITING THE DIVIDED INTESTINE."

BY G. LENTHAL CHEATLE, F.R.C.S. ENG.,
ASSISTANT SURGEON TO KING'S COLLEGE HOSPITAL AND TO THE WEST LONDON HOSPITAL.

IN THE LANCET of May 22nd, 1897, I described a method of uniting the divided intestine the essential features of which were two incisions, one placed in each extremity of the divided ends, and opposite to, as well as parallel with, the mesenteric attachment, so that they enable the operator to sew together the separated ends of the canal with their serous surfaces in perfect apposition. It will be seen that when the ends of the intestine are thus joined one longitudinal opening must necessarily result (see Fig. 1), and I described how this aperture was stitched up as a longitudinal one. This, like most other methods of intestinal resection, leaves the lumen of the canal smaller than normal, and the size of the tube must be still further diminished by the subsequent contraction of the encircling cicatrix. To prevent stricture is a great source of difficulty. Any procedure that has for its objects diminution of the stricture as well as the union of the divided ends must be worthy of consideration. By altering the treatment with regard to the longitudinal opening (see Fig. 1) I hope to make the above method

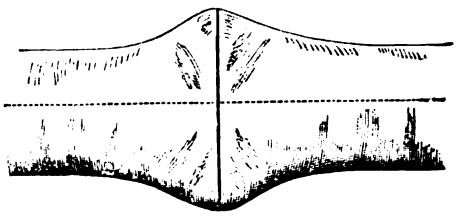


FIG. 1.

Showing the longitudinal opening into the gut after union of the cut ends. It is placed opposite to, and parallel with, the mesenteric attachment. The latter is represented by a dotted line.

accomplish the former object as certainly as it does the latter. In my most recent operations upon dogs I have brought the extremities of the longitudinal aperture (see Fig. 1) into apposition, and thus fixed them and then sewed up the opening that had thereby been made transverse to, or at right angles with, the attachment of the mesentery (see Fig. 2).

FIG. 2.

Showing how the longitudinal opening has been made continuous with the united ends by converting it (the longitudinal opening) into a transverse one by having brought its extremities into apposition and its fixation in that direction. The mesenteric attachment is represented by the dotted line.

And hence nearly the whole length of the previously longitudinal aperture is thrown into the continuity of the lumen, which must necessarily increase its size. Halsted's square stitch I find the best for this purpose. It will be remembered that in non-malignant strictures of the pyloric end of the stomach a longitudinal incision is purposely made into the strictured parts in order to convert it into a transverse one, and Mr. Allingham has done the same thing in similar strictures of the intestines.

Harley-street, W.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The first meeting of the sixteenth session of this society was held at the West London Hospital on Oct. 8th, 1897. The President, Dr. H. P. Potter, read the opening address entitled "Some Aspects of Heredity," which was received with much appreciation by the members, who had attended in a good number. A vote of thanks was proposed by Mr. C. B. Keetley and seconded by Dr. Symons Eccles and carried unanimously. Dr. Potter replied in a few appropriate words. The officers for the ensuing year are:—President: H. P. Potter, M.D. Durh., F.R.C.S. Eng. Vice-Presidents: C. Wells, M D. R U.I., Swinford Edwards, F.R.C.S. Eng., Donald Hood, M.D. Cantab., F.R.C.P. Lond., R. J. Bannig, M D. St. And., A. Symons Eccles, M.B. Aberd., Bruce Clarke, F.R.C.S. Eng., R. Lake, F.R.C.S. Eng., W. H. Lamb, M B Lond., A. G. Wells, M.R.C.S. Eng., and C. M. Tuke, M R.C.S. Eng. Council: L. A. Bidwell, F.R.C.S. Eng., H. Des Vœux, M.D. Brux., William Hunter, M.D. Edin., F.R.C.P. Lond., F. Lawrence, M.R C.S. Eng., Herbert Menzies, M.R.C.S. Eng., Seymour Taylor, M.D. Aberd., M.R.C.P. Lond., Andrew Elliot, M.D. Edin, F. H. Low, M.B. Aberd., G. H. D. Robinson, M.D., M.R.C P. Lond., James Harper, M.D. Lond., C. Andrews, M.R.C.S. Eng, and Neville Wood, M.R.C.P. Lond. Treasurer: T. G. Alderton, M.R.C.S. Eng. Secretaries: F. J. McCann, M.D. Edin., M.R.C.P. Lond., and W. McAdam Eccles, M.S. Lond., F.R.C.S. Eng. Librarian: C. B. GENERAL HOSPITAL, GREAT YARMOUTH.

A CASE OF TETANUS TREATED WITH TETANUS ANTITOXIN; DEATH.

(Under the care of Dr. H. BLAKE.)

THE discovery in 1885 by Nicolaier of the bacillus of tetanus did much to systematise the treatment of the disease. Amputation had fallen into disuse, as it was found that it rarely succeeded in saving the life of the patient; but now in suitable cases it is an important method of treatment, as it has been conclusively shown that the bacillus is only found in the neighbourhood of the wound, and its presence in the blood or the central nervous system has never been demonstrated. In amputation, however, there is very great risk of inoculating the amputation wound with the bacilli from the original wound or of making the incisions through tissues too close to the site of infection. The value of tetanus antitoxin in certain cases is practically beyond dispute, but in some instances, as in the following, it fails, and we are still in want of exact indications as to the amount of the antitoxic serum which it is desirable to inject. For the notes of the case we are indebted to Dr. F. M. Fellows, house surgeon.

A boy, aged nine years, was admitted to the General Hospital, Great Yarmouth, on Oct. 2nd, 1897. The patient had fallen under a van and the wheel had inflicted an extensive lacerated wound on the inner side of the right knee, opening into the joint. There was great laceration of the soft parts and they were much ingrained with dirt; but, taking into account the age of the patient, it was decided to make an attempt to save the limb. An anæsthetic was accordingly administered and the wound was thoroughly disinfected. Under antiseptic treatment with continuous irrigation of the joint, the patient made good progress up to the 13th, the local condition improving and the temperature being kept within bounds On the evening of the 13th, however, it was noticed that the patient had difficulty in opening his mouth. The masseters were then found to be in a state of tonic contraction, and there was some stiffness of the muscles of the neck, back, and abdomen. The temperature was 99° F. Amputation above the knee through apparently healthy tissue was performed at 10 P.M. and a supply of tetanus antitoxin was telegraphed for. On the 14th he had passed a good night; the temperature was 100·2°, the pulse was 136, and the respiration was 24. The masseters were slightly less rigid, but there was commencing risus sardonicus. 20 c.c. of tetanus antitoxin were injected under the skin of the abdomen in two doses, one at 3 P.M. and one at 11 P.M. On the 15th there was rather more stiffness of the masseters and of the muscles of the face, neck, and abdomen, as well as slight opisthotonos and commencing stiffness of the muscles of the extremities. The temperature was 99·4°, the pulse was 132, and the respiration was 24 29 c.c. of antitoxin were administered in three doses at 7 A.M., 4 P.M , and 12 midnight. On the 16th he had passed a bad night. Two tetanic convulsions, affecting the muscles of the face, neck, and upper extremities, occurred during the night. Food by the mouth brought on a tendency to these convulsions, and rectal feeding was accordingly substituted. The temperature was 100·8°, the pulse was 120 and weak, and the respiration was 24 and laboured. 30 c.c. of antitoxin were injected under the skin of the thigh in three doses at 8 A.M., 12 noon, and 8 P.M. Several partial convulsions, as above described, occurred during the day, but never a general tetanic convulsion. All the symptoms became aggravated. The temperature went up steadily to 105°, the pulse could not be counted after 2 P M., and the patient was evidently dying. Death took place at 11 P.M., the temperature immediately after death being 108°.

Remarks by Dr. FELLOWS.—Although the incubation period was long—eleven days—the disease ran a rapid course, killing the patient in four days. The amputation appeared to delay the progress of the disease, but the course of the disease was apparently quite unmodified by the antitoxin. I should be glad if any readers of THE LANCET could inform me if the bacillus of tetanus has ever been discovered in the general circulation or anywhere in the body at a distance from the site of inoculation. The antitoxin used was that supplied by the British Institute of Preventive Medicine; it produced no local irritation or febrile reaction.

LIVERPOOL STANLEY HOSPITAL.

A CASE OF HERPES; GANGRENE; DEATH.

(Under the care of Mr. DOUGLAS CRAWFORD.)

FOR the notes of the case we are indebted to Mr. F. Deas, senior house surgeon.

A patient, aged four years, was brought to the out-patient department of the hospital on August 24th last. He was then suffering from well-marked herpes, which was limited very exactly to the area of skin supplied by the twelfth dorsal nerve on the left side.[1] The eruption had then been out for a little over a week and showed three characteristic stages. It had commenced near the middle line of the back and gradually spread round to the front. The lesions appeared first as groups of papules on an inflamed base; these soon became vesicular, and when seen many of the vesicles were purulent and many groups had coalesced. All three stages were well seen. None of the vesicles had yet burst. The inflammation was well marked and had spread slightly into neighbouring skin areas. The child complained of acute burning pain in the affected area. The mother said that before the rash came out the child complained of pain in the bottom of his back. The mother gave a syphilitic history, and the child showed many signs of congenital syphilis. The child was put on quinine mixture, and was also given two grains of pulvis hydrargyri cum cretâ every morning. A local application of weak lead lotion with liquor carbonis detergens was also ordered. Mr. Deas saw the child again a week later, and then all traces of the characteristic eruption had disappeared. Instead, the skin area affected presented many patches of gangrene varying in size from that of a threepenny-piece to that of a crown. The inflammation was intense in the patches of skin intervening between gangrenous portions. The child looked extremely ill, but did not appear to suffer much pain. The diseased skin gave forth a horrible necrotic odour. The mother refused to leave the child in the hospital, but brought him again two days later, when he was admitted. He was then evidently suffering from the effects of septic absorption. The gangrenous patches had nearly all coalesced. Every effort was made to get rid of the dead skin and subcutaneous tissue by removal and hot boracic fomentations, but the child never rallied and died from septic poisoning four days after admission. While in the hospital the temperature varied between 99° and 101° F.; just before death it was 102°. The patient had diarrhœa during the last two days.

Remarks by Mr. DEAS.—I suppose the gangrene to be due to vaso-motor paralysis, being a further stage of the cutaneous neuritis. Death from herpes zoster is rare in any case, though more or less extensive sloughing is not very uncommon. Probably the case would not have had a fatal termination had the child been left in the hospital at the commencement of the attack. Unfortunately the body was removed a few hours after death, and I could not get a post-mortem examination.

HERTFORD BRITISH HOSPITAL, PARIS.

RECOVERY UNDER DIGITALIS IN LARGE DOSES IN A CASE OF APPARENTLY IMMINENT DEATH.

(Under the care of Dr. ALAN HERBERT.)

IT is undoubtedly the fact that even small doses of digitalis will materially modify the action of the heart, strengthening the force of the contraction and diminishing the frequency of

[1] Vide Quain's Anatomy, vol. iii., part ii., p. 346.

Digitized by Google

the beat, but it is often noticeable that this action of the drug does not manifest itself for two or three days after the commencement of the administration. When a more rapid effect is desired the amount of the dose must be increased, or, what is better, the same dose must be administered more frequently. The innocuousness of very large doses of digitalis under certain circumstances was first pointed out by Mr. Jones, of Jersey, who gave half an ounce of the tincture for delirium tremens, and repeated it if necessary after four hours and again in six hours. In many cases the effect was marvellous, the pulse improved, and sound sleep followed, but in a few cases sudden fatal collapse occurred, and it is probable that these fatal cases, though the death had not necessarily been the result of the digitalis, led to an almost complete disuse of these very large doses of digitalis. In Dr. Alan Herbert's very interesting case the failure of the heart was marked, and, as the result showed, it needed much larger doses of digitalis than are usually given. For the notes of the case we are indebted to Dr. A. A. Warden.

A man, aged forty-six years, was on Oct. 11th, 1897, admitted into the Hertford British Hospital, Paris, under the care of Dr. the Hon. Alan Herbert, in a state of extreme weakness, with a rapid, irregular heart, some œdema of the feet and hands, and passive congestion of both lungs. The patient had had "pleurisy" two years before and had been in hospital at that date with a definite though slight tuberculous lesion of the left lung. Little alteration, according to the nurse's report, took place in his condition until the evening, when Dr. Warden was suddenly sent for on account of an increasing difficulty in breathing. It required little more than a glance to grasp the fact that the man was apparently dying, and dying rapidly. His face was dusky and grey rather than livid, and, with his neck and chest, was bathed in perspiration. The loud tracheal rattle and laboured respiration as he rolled his head in distress from side to side made auscultation valueless. The cardiac impulse, however, irregular and soft, could be felt by the palm of the hand. His pulse was a mere flicker, exceedingly rapid and irregular both in force—an occasional beat being almost surprisingly strong to the finger on the radial artery—and in rhythm, many of the cardiac beats being apparently imperceptible at the wrist. His extremities, especially the legs, were cold. The nurse had at once given him half an ounce of brandy, which, however, was promptly vomited with some slops taken about an hour before. The patient had spent the previous week in Paris, out of work, with practically nothing to live on, and, medically speaking, altogether untreated. So far, therefore, therapeutics had a fair field. At once a hypodermic injection of $\frac{1}{15}$ gr. of strychnine was given, and almost immediately a second injection of 30 minims of ether, while half an ounce of brandy was given by the mouth. This happily was retained, as was all further medicine. Two mustard leaves (about 5 in. by 3 in.) were applied over the heart and six mustard leaves upon each leg along the thighs and calves, with hot bottles to the feet. He was then put upon 20 minims of the tincture of digitalis in 2 teaspoonfuls of brandy every quarter of an hour. These measures were continued, with some irregularity owing to the patient's condition and the difficulty in getting him to swallow the stimulant, from 8.45 P.M. until midnight. In the space of these three and a quarter hours he had taken 3 dr. of the tincture of digitalis and 2$\frac{1}{2}$ oz. of brandy. The result at that hour was appreciable, and as he complained of intense headache and there seemed nothing to gain by supplying stimulant more rapidly than it could be absorbed both the digitalis and the brandy were stopped and milk and soda-water given to relieve his thirst. At 2 A.M. his condition had vastly improved, his respiration being deeper and less laboured, the tracheal rattle less distressing and loud, and the pulse, though scarcely less rapid, was far more regular both in rhythm and in force. His bowels were moved four times in the course of the night, twice spontaneously, the patient being too weak to call forth the action of his sphincters. A specimen of urine which was passed was found to be very smoky and blood-coloured, and the microscope showed abundant red corpuscles. No casts could be detected, but a small amount of albumin was present, such as might have been entirely due to the amount of blood present. The urine was alkaline in reaction, with a specific gravity of 1012. About 4 A.M. he vomited twice, but it immediately followed a drink of milk and soda-water and was not even tinged yellow, as might have been expected. At 9 A.M. he was evidently out of immediate danger. On the evening of Oct. 12th his temperature rose to 101·2°, his pulse varying through the day from 104 to 130 beats per minute. The hæmaturia continued, 20 oz. of urine being passed in the first eighteen hours, some, however, being lost on account of the diarrhœa present. By the 14th his temperature had fallen to normal, his pulse was beating steadily at from 86 to 92 per minute, the urine amounted to 70 oz. in the twenty-four hours, and the lungs were very much clearer.

Remarks by Dr. WARDEN.—I venture to call attention to the following points and would be grateful for the opinion of any therapeutic *maitre* upon them: 1. The digitalis did not slow the pulse so much as it regulated it in every way. It cannot be said to have caused the vomiting which occurred, and the diarrhœa certainly began before the patient had taken more than 30 minims and had quite ceased by the morning of Oct. 12th. Headache and thirst, both of an extreme degree, seemed to follow the use of the drug. Had he vomited recourse must have been had to hypodermic injections of digitalin. 2. The apparent innocence of such doses—toxic according to the British Pharmacopœia; huge according to the general practice of the day—suggests the query, still unanswered satisfactorily I think, Is the regulation dose of 5 or 10 minims three times a day sufficient to affect appreciably the human heart? 3. Can the somewhat heroic treatment so hastily put in force account for the hæmorrhage from the kidneys which, in all probability, were in a state of passive congestion? That there was no vesical congestion is proved by the tolerance of distension shown by the bladder.

Calcareous Metamorphosis of the Tracheal Lymphatic Glands leading to Perforation of the Arch of the Aorta.—Pathology of Pernicious Malarial Fevers.

A MEETING of this society was held on Oct. 26th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Dr. SIDNEY PHILLIPS read a paper on a case of Calcareous Metamorphosis of the Tracheal Lymphatic Glands, leading to Mediastinal Abscess and the Formation of a Bronchial Fistula and to Perforation of the Arch of the Aorta. The patient was a man, twenty-six years of age, who during two years before the onset of chest symptoms had suffered from several attacks of rheumatism. In 1887 while riding he was seized with intense pain round the right third intercostal space, with hyperæsthesia of the skin of the chest as far down as the sixth rib without any physical signs of disease in the chest. Eleven days later he had a series of rigors followed by sustained pyrexia, the pain continuing. There was a little friction heard on the eleventh day at the left back, and a month later incessant spasmodic dry cough due to irritation of the laryngeal nerves. Suddenly pleuritic effusion occurred into the left pleura and repeated aspiration of clear fluid was necessary. Later there was evidence of the existence of the free air in the pleural cavity and for the first time a small quantity of pus was expectorated. As his breathing was much embarrassed and there were frequent syncopal attacks which threatened life a free incision was made by Mr. Godlee into the pleural cavity and fluid was evacuated. The patient's condition at once improved and he gradually returned to a fair condition of health. He continued well except for some wheeziness of breathing until eighteen months later, when he had sudden severe hæmoptysis. This occurred again and again during a period of eighteen months, till he died from hemiplegia. The necropsy showed the presence of a small tumour at the tracheal bifurcation composed of adherent calcareous glands. In the substance of this tumour an abscess had formed and discharged through the right bronchus, leaving a permanent fistulous opening into it. A perforation had also been formed by erosion between the calcareous mass and the arch of the aorta, the aorta being thus brought into communication with the abscess cavity, and so indirectly with the bronchus. Dr. Phillips commented on the difficulties of diagnosis, and on the remarkable fact that an aperture should have existed for

Digitized by Google

so many months in the aorta only a few inches from the heart without causing death earlier.

Dr. THIN contributed a paper on the Pathology of the Pernicious Malarial Fevers of Sierra Leone. In February, 1896, Dr. Thin contributed to the society a note on the appearances found in the tissues in a fatal case of pernicious malaria at Sierra Leone. Since then he had examined tissues in three additional cases of pernicious malaria occurring at Sierra Leone, and in a case of pericarditis not complicated with malaria. In the case of pericarditis no parasite and none of the effects produced by the parasite of malaria were found. He described in detail the condition of the tissues in the three additional cases of malarial poisoning, and summarised the results found in these and the previous case. In the pernicious malarial fevers of Sierra Leone the disease is caused by the development of very great numbers of parasites in the capillaries of the brain. Each parasite in its earliest stage is a very minute, round, nucleated, protoplasmic structure, the diameter of which is about a fourth or a fifth of that of the red corpuscle. As it develops from three to five and sometimes a greater number of spores are formed. The sporulating parasite is comparatively small, in sections of hardened and shrunk tissue not filling more than from a third to one-half of the red corpuscle, and with a disproportionately large amount of central pigment. Small cerebral hæmorrhages are sometimes found surrounding a blood-vessel which contains parasites, the wall of the vessel being probably weakened as a result of the degeneration of the endothelium which is associated with the absorption of pigment. Very few parasites were found in other organs, and these only in the early stage. The veins of the brain and pia mater contain large numbers of white corpuscles loaded with pigment and débris of the parasite The splenic pulp contains great numbers of pigment-laden white corpuscles, which are also found in considerable numbers in the splenic veins and perivascular lymphatic spaces. The lymphoid tissue of the spleen contains very few, and the Malpighian corpuscles none. The blood-vessels of the liver are more or less congested. In one case the capillaries were very greatly distended with blood. The endothelial cells of the capillaries in the liver contain much pigment, and those that contain pigment are degenerated and broken up. Pigment is found outside the capillary wall accumulating in blocks, and very large blocks are found in the interlobular perivascular spaces, presumably partly or entirely in lymphatic vessels, although the walls of such vessels were not seen in the sections. Pigment is also taken up by the liver cells, and the liver cells so affected undergo changes. The first stage in the morbid process is an enormous production of parasites in the brain. The last stage is an accumulation of pigment in the interlobular tissue of the liver, where in cases that recover it is probably destroyed and absorbed. Morphologically, the parasite of these fevers is distinct from the parasites of the quartan and tertian fevers and resembles that described by Marchiafava in the summer-autumn fevers of Southern Italy. The appearances in the spleen and liver correspond with those described by Bignami in fatal cases of malarial fever in Italy, but in the Sierra Leone cases no formation of crescent bodies had taken place up to the time of death, and none of the characteristic appearances in young parasites which are associated with a subsequent development of crescents were observed. Nothing was seen that would indicate that the blood in the spleen was more infected than the peripheral blood, or that the splenic tissue was a special nidus for the parasite. In the four cases examined the breeding place was the brain, which accounts for the symptoms observed during life. In connexion with the special selection of the brain by this parasite Dr. Thin called attention to the comparatively small size of the cerebral capillaries, their calibre not being much more than half that of the capillaries of the other parts of the body, and being scarcely equal to that of a red corpuscle. It is known that the infected red corpuscle adheres to the vascular wall, as is seen in the small veins. This tendency to adhere to the capillary endothelium, in conjunction with the small calibre of the cerebral capillaries, must favour their being blocked by the infected corpuscles. Dr. Thin suggested that the arrest of the infected corpuscles in these fevers in the brain capillaries, while the infected corpuscles in tertian and quartan fevers are not arrested in them, may be due to the greater toxicity of the parasite in these fevers which affects the red corpuscles more severely and renders them more adherent to the endothelium. The blocking once begun will be furthered by the short cycle of development of the parasite — Dr. N. DALTON said that at the meeting of the British Medical Association at Bristol in 1894 he had shown sections of the liver in pernicious cases of malaria in which he had demonstrated the same changes in the endothelium and pigmentation of the connective tissue that Dr. Thin had now shown in association with the life-history of the parasite. The dilatation of the capillaries appeared to be permanent, the cells being found flattened just as in nutmeg liver, and he thought that the condition might lead to the development of interlobular cirrhosis. Possibly the extensive blocking of capillaries described might account for the cases in which high arterial tension without kidney disease was found after long residence in malarial districts.—Dr. JOHN ANDERSON said that information was wanted to explain the abundance of the parasites in the capillaries of the brain in these pernicious cases. In the anomalous cases which were described as a typho-malarial type, and which yielded so slightly to quinine, he thought that cerebral symptoms were more frequent than in the ordinary tertian and quartan forms. He mentioned two cases of people who had returned home after suffering severely from severe forms of malaria abroad, and were now liable to cerebral complications when there was any return of fever, one patient having intense pain in the head, and often delirium, and the other severe vertigo. He found these severe cases apt to resist quinine, but they yielded to arsenic. He often gave very large doses, as much as a drachm, of the liquor sodæ arseniatis three times a day, and the drug was well tolerated. Such doses had also been found useful in pernicious cases by Sir Anthony Home in the Ashanti campaign of 1873, and by Surgeon-General Taylor in the recent Ashanti expedition.—Dr. THIN said that there was a general consensus of opinion that in the pernicious forms of West African fever quinine in large doses was the best remedy. As much as twenty grains might be given every two hours. Unless large quantities of the drug were quickly introduced to kill the parasites they would destroy the patient. What was wanted was some preparation of quinine which could be injected subcutaneously without causing pain. Baccelli had used intravenous injections in some severe cases of Roman fever. He thought that the best treatment of people who were subject to a return of malaria was the continuous administration of moderate doses of quinine and arsenic. There was a troublesome group of patients who were invalided home with "climatic debility" who had never had any rise of temperature and were not supposed to have had malaria, but a prolonged examination of the blood rarely failed to show the presence of the parasite.

MEDICAL SOCIETY OF LONDON.

The Localisation of Rheumatism and Chorea.

A MEETING of this society was held on Oct. 25th, the President, Dr. SANSOM, being in the chair.

Dr. CHURTON (Leeds) read a paper on the Localisation of Rheumatism and Chorea. He said there were nearly 600 cases tabulated, and the state of health before the attack, the assigned causation, and the joints first affected, the occurrence of acetonuria, indicanuria, and constipation were noted. The previous health was decidedly not good in a great majority of cases; when alleged by the patient to be good it was far from perfect, and usually meant that he was not absolutely incapable of work. The causes assigned were chiefly wettings and injuries; in some of the cases in which no causation could be assigned indicanuria was found. It was constantly observed that the joints of those limbs which were chilled or injured were the first to suffer. There was no positive exception to this rule, although in a few cases—probably owing to imperfect information—there were apparent exceptions. But a case which recently occurred showed the necessity for caution A girl, aged twenty years, whose disease began with pain in or about the right lower ribs, was quite unable to give any reason for this until repeated examinations of herself and her friends elicited the fact that after four weeks of unusually hard work at a mill three miles from her home she had hurriedly washed her head and chest one morning at six o'clock, dried her hair very imperfectly, had no time for breakfast, ran most of the way to the mill, worked from 7.30 A.M. to 2.30 P.M.

Digitized by Google

without food, and then walked home extremely tired. The same evening pain in the side and all over the head began; afterwards her shoulders and other joints were affected. In 21 cases of rheumatism in 1896 when more care was taken in sifting the evidence obtained, 14 clearly displayed the relation; in 7 it was not precise. In 3 it was a damp house; in 1 it was damp clothing; in another case the patient was a negro circus rider; in another case a miner; in the seventh the patient was a child addicted to eating sweets and ices; she had rheumatism in the lower limbs; acetone was abundant in the urine. The "toxin-local injury" theory of rheumatism had been held by Sir Dyce Duckworth and others. The toxin may perhaps be glycocine (Latham); if so the microorganism would not be found where it has been sought—in the blood, joints, &c. Moreover, disorder of the digestive epithelia and muscles may well be caused by shock to the brain; hence the rheumatic toxin may hereafter be found to be caused indirectly and the localisation of its effects directly by the same shock, or the latter by either simultaneous or subsequent chills or injuries. In 150 cases of chorea tabulated it was with respect to most of them impossible to reply to the questions—How is the connexion of the chorea with rheumatism shown? And even when the patient was admittedly rheumatic, why was the action of the toxin diverted to the brain? A few of the cases, however, showed the localising power of shock in rheumatic patients, thus bringing chorea more sharply into line with arthritis in this respect. Case 1. A man, aged twenty-three years, had chorea when eleven years old. In June, 1896, he had rheumatism of the knees. After a quarrel chorea began. Case 2. A boy, aged fourteen years, had been ill ten weeks with rheumatic fever. A school-board officer hurried him to school during convalescence; in a fortnight chorea appeared. 3. A boy, aged nine years, had had rheumatic fever twice. On Dec. 1st, 1891, he was startled by a man leaping out of an ash-pit in the dark and seizing his arm; chorea began next day, and two or three days afterwards arthritis. Case 4. A man, aged eighteen years, in October, 1895, had subacute arthritis in the knees after kneeling in wet sand. He had nearly recovered when he quarrelled violently with a relative; next day chorea appeared in the right face and limbs. Three days after this the right hand was painful and swollen for five days, when the chorea and pain were nearly gone. Another quarrel then occurred; next day chorea returned in the right hand and quickly spread through all the limbs. In a girl, aged eighteen years, the child of an alcoholic father, overwork in an insanitary house was followed by chorea and arthritis. She became sullen and apparently insane, but recovered under the free administration of port wine after failure of other means including inhalation of chloroform with morphia hypodermically. In the cases tabulated there was no instance of chorea primarily caused by chill and no case of arthritis primarily caused by fright.

Dr. STEPHEN MACKENZIE said that the investigation of rheumatism up to the present had been largely statistical. The method of detailed examination of individual cases adopted by Dr. Churton in his paper would be of the greatest value to future investigators. Dr. Cheadle in his book on Rheumatism in Childhood had shown the sequence of events that occurred in rheumatism traced through the life of several patients. He agreed that rheumatism was not expressed only by arthritis and pyrexia, but by inflammations of the serous membranes, cutaneous eruptions, subcutaneous nodules, and, of course, chorea. The localising effect of various causes had been brought out by Dr. Churton. He agreed that, as a rule, chill and wetting determined affection of the joints, while cases of chorea were chiefly excited by fright. Another localising factor was the age of the patient, chorea being common in children, while arthritis was rare. Possibly the occurrence of chorea in growing children was largely due to the instability of the brain during the period of rapid development, but he knew of no reason for the incidence on the joints in adults. Apart from any possible microbic infection there was in many persons an inherited proclivity to rheumatism. With regard to the previous history of the patients he had been struck with the infrequency of anæmia as an antecedent, although it so often followed as an effect. He expressed his emphatic belief that chorea and arthritis were equally manifestations of rheumatism, although the term rheumatism still required to be defined.

Dr. ARCHIBALD GARROD thought that the localising influence of an exciting cause was seen in an even more striking manner in gout than in rheumatism. He quoted two cases in one of which an attack of gouty eczema followed the application of belladonna liniment and in the other a severe gouty inflammation of the pinna occurred after the ear had been syringed. The grouping of rheumatic manifestations was curious. Chorea and endocarditis were frequently found together, and erythema often occurred in association with arthritis, but erythema was rarely complicated by endocarditis. Pericarditis was nearly always present in severe cases, such as those accompanied by much pyrexia or rheumatic pneumonia. He thought that injury and excessive exertion were very important factors in the localisation of the joint affection. With regard to the influence of fright as an exciting cause of chorea it should be remembered that an emotional condition was as much a symptom of chorea as the motor disturbance, and it was often the emotional condition produced by the chorea that caused the child to be severely frightened by a quite inadequate cause. A history of rheumatism was often unobtainable in cases of chorea, but in children rheumatism was often latent as in one case under his observation in which for four years the only indication of rheumatism was the occurrence of successive crops of rheumatic nodules.

The PRESIDENT read a letter from Sir Dyce Duckworth expressing the strong conviction that arthritis and chorea were two manifestations of the same morbid process. The President added that he himself did not share that view.

Dr. C. W. CHAPMAN quoted a case in which fatal chorea in an adult followed his being garroted.

Dr. C. H. F. ROUTH referred to the changes of type of rheumatism, gout, and other diseases that had occurred within his recollection. He believed that both rheumatism and chorea were due to some acid circulating in the blood, and that they were best treated by the free administration of alkalies. He believed that climatic influences and atmospheric electricity were important factors.

Dr. FLETCHER LITTLE observed that it was often difficult to trace the localising factor and quoted the case of twin sisters who both suffered from neurasthenia and one of them developed arthritis in all her joints, while the other, although exposed to precisely the same influences, remained entirely free from joint trouble. He remarked on the occurrence of epidemics of chorea without special climatic conditions; he thought that there was also an epidemic tendency noticeable in the occurrence of rheumatism as a complication of scarlet fever.

Dr. CHURTON, in replying, mentioned a case in which right brachial monochorea followed a blow on the left side of the head. Dr. Mackenzie's reference to anæmia as a post-rheumatic symptom suggested that anæmia may be one of the signs of pre-existing rheumatic poisoning in choreic children. The cloudy swelling of the pyramidal brain cells mentioned by Sir Dyce Duckworth was strongly suggestive of irritation by a toxin. Probably the urine would hereafter supply further evidence. In heredity the patient's proclivities to disease did not follow those of the parents at random, but only the proclivities of the parent whom the patient most closely resembled.

CLINICAL SOCIETY OF LONDON.

Congenital Dislocation of Both Hips on to the Pubes — Primary Tuberculosis of the Nares — Nævus of the Frontal Region. — Hemiplegia in an Infant — Paraplegia with Multiple Subcutaneous Tumours. — One-sided Blushing on Eating. — Pylorectomy for Cancer of the Pylorus. — Coxa Vara in an Adolescent.

A CLINICAL meeting of this society was held on Oct. 22nd, the President, Mr. LANGTON, being in the chair.

Mr. W. H. BATTLE showed a female infant, twelve months of age, with Congenital Dislocation of Both Hips on to the Pubes and Congenital Dislocation of the Right Humerus. The child was born after breech presentation, but he was unable to say if there had been any injury at birth. The child lay on her back with both thighs abducted and everted. There was very little difference in the attitude of the two limbs; the groins appeared full, while the buttocks were flat. When the child was lifted up the thighs remained abducted and everted. There were signs of an acetabulum of the right side, but none had been discovered on the left. On the right side the dislocation could easily be reduced,

Digitized by Google

but it immediately returned. On the left side the head remained on the pubes and was apparently ill-formed. There was also a sub-coracoid dislocation of the right humerus with atrophy of its upper end.—Mr. JACKSON CLARKE said that in specimens which had been dissected there had usually been an acetabulum, although only a small one. He thought that this was a suitable case for Lorenz's operation, if it were performed early.—Mr. MAKINS remarked that the dislocation in all three joints was forward. It was difficult to see how injury at birth could have produced them.—The PRESIDENT observed that for some reason these cases were much more common among female children.

Dr. ST. CLAIR THOMSON showed a woman, aged twenty-five years, who about two years ago began to suffer from nasal discharge and blocking of the right nasal passage. She then presented a smooth, bluish-pink, sessile growth the size of half a filbert on the right nasal septum, which was removed, and when examined histologically was found to be a tuberculous growth, though no bacilli were discovered. The growth had begun to caseate and break down in the centre. A year ago the tuberculous deposit had spread through to the left side, appearing there as a pale pink uneven outgrowth. She was treated with repeated curetting and application of lactic acid to the septum and inferior turbinal on either side. She also had three injections of Koch's tuberculin about a year ago. The patient had come under Dr. Thomson's care six months ago. She then had a perforation of the cartilaginous septum, pale indolent ulceration of both inferior turbinals, and in the centre of the buccal pharynx was a flat swelling about the size of a shilling with an ulcerating surface. There was an adhesion between the left inferior turbinal and the septum, and the perforation in the septum was surrounded by pale hypertrophic tissue covered by crusts. A portion of this was removed with a snare, and the sections—which were placed under the microscope—showed it to be infiltrated with tubercle, the giant-cell systems being well marked with foci of caseation. Sections were stained and examined for tubercle bacilli, but after prolonged search no bacilli were detected. Applications of lactic acid set up some reaction and excited adhesions between the opposite sides, so that everything was abandoned locally except cleansing alkaline lotions. The upper part of the pharynx being atrophic from the interference with the normal functions of the nose daily applications of Mandl's solution of iodine and iodide of potassium were ordered. Under this treatment the pharynx had considerably improved; the tuberculous thickening had shrunk considerably, while the abraded surface was not as large as a threepenny-piece. The improvement to the pharynx was so decided that the same iodine preparation was applied to the inside of the nose, pledgets of cotton-wool being soaked in it and left *in situ* on either side for from five to ten minutes. The patient was healthy-looking and there was no trace of trouble in her lungs. She had admitted being addicted to the habit of picking her nose, and he suggested that this had opened the door to infection. — Dr. SCANES SPICER said that he had examined the nose and could not satisfy himself that the lesion was tuberculous. There was much hypertrophic growth about the septum, but it did not appear to be more than ordinary granulation tissue, which it would relieve the patient to have removed.—Dr. KINGSTON FOWLER protested against an absolute diagnosis that a tissue was tuberculous if, as in this case, no tubercle bacilli were found. Structures indistinguishable from typical "tubercle follicles" were found in other conditions. It had been mentioned that tubercle bacilli were usually present in the nostrils, but he thought that this was open to question.—Dr. WHITFIELD thought that the fact that the patient had reacted to Koch's "old" tuberculin was in favour of the lesion being tuberculous. He suggested that Koch's "new" tuberculin should be tried.—Dr. ST. CLAIR THOMSON, in reply, remarked that in lupus there was often the greatest difficulty in demonstrating the tubercle bacillus. In his case he thought that the pathological and clinical evidence justified a diagnosis of tubercle.

Dr. ST. CLAIR THOMSON also showed a man with a very distensible Nævus of the Frontal Region, with Defect in the Subjacent Bone. The patient was a man, fifty years of age, and in the centre of his forehead was a vertical, depressed, bluish, cicatrix-like surface, about half an inch in length and a quarter of an inch in width. Beneath its surface the smooth, level frontal bone could be felt to be replaced by a depressed surface, which was rough and tender. To the left of this, starting from above the left of the glabella and passing obliquely upwards and outwards for one and a half inches, the skin was seen to be bluish and wrinkled, with a central, somewhat puckered depression. On palpation the bone immediately below this nævus was felt to be hollowed out, the rough floor of the hollow being some depth below the ordinary level of the frontal bone and very tender to the touch. When the patient talked this blue depressed surface was seen gradually to unfold itself and to rise above the level of the adjoining skin; if he strained in any way or blew his nose it swelled out into a round, blue tumour as big as a pigeon's egg. The patient had himself observed that it was always very prominent if he got in a passion. The smaller central nævus also became prominent, but to a lesser degree. There was no pulsation or thrill over this nævus. It was thought at first that there might be a complete defect of the anterior wall of the frontal sinus, and that the swelling was due to the distension of the frontal sinus with air, but there was no tympanic resonance over the swelling, and it could not be distended with air inflated into the nose with a Politzer's bag while the patient swallowed or held his breath. He was therefore disposed to think that either the whole of the anterior wall of the frontal sinus was not affected or else that this curious defect in the bone was not situated over the frontal sinus, but that it involved only the outer table of the frontal bone higher up than the situation of the sinus.

Dr. BERTRAM ABRAHAMS showed a child, two years of age, suffering from Hemiplegia. The hemiplegia occurred during the first few days of whooping-cough, but at the time the cough was by no means severe. The onset was sudden. One evening she was seized with an attack of right-sided convulsions and was unconscious; the pupils were dilated and insensitive to light, and there was marked nystagmus. There were several slight convulsions on the following day. The temperature during the convulsive attack was 103° F. A day or two later she presented complete right hemiplegia and aphasia. There was at present partial hemiplegia, more recovery having taken place in the leg than in the arm. The heart was normal, but there was slight albuminuria. Dr. Abrahams thought that the balance of evidence was more in favour of hæmorrhage than embolism. — Dr. G. A. SUTHERLAND recalled a case in which the onset was very like that described in this case, but which turned out to be one of tuberculous meningitis with an acute onset. He thought that hæmorrhage in the brain often occurred when the cough was of quite moderate intensity.

Dr. JAMES COLLIER showed for Dr. BUZZARD a man, thirty years of age, suffering from Paraplegia with Multiple Subcutaneous Tumours. Two years previously the patient complained of pain and stiffness in the left leg and afterwards in both legs. The paraplegia had slowly increased since that time. Soon after the onset painless nodular subcutaneous tumours developed and slowly increased, becoming as large as a Spanish nut. They were situated over both trochanters, over the ulna on both sides, and over the right external malleolus on both sides. Under iodide of potassium the nodules over the ulna and the fibula had disappeared, but those over the trochanters had persisted. In addition to the spastic paraplegia there was some loss of control over the sphincters and there was anæsthesia over areas corresponding to the fourth and fifth sacral and fifth lumbar roots on the left side. A history of syphilis could not be elicited, but there was evidence of past iritis. The administration of large doses of mercury and iodide of potassium during the last month had not been followed by any improvement in the paraplegia or any diminution in the size of the tumours.—The PRESIDENT regarded the case as one of syphilitic disease of certain adventitious bursæ. Under iodide of potassium such tumours usually subsided to some extent, although they rarely disappeared.—Sir DYCE DUCKWORTH also thought that the case was one of late syphilis.

Dr. PARKES WEBER showed a curious case of One-sided Blushing on Eating. The patient was a young man who exhibited a curious localised blush on the left cheek on eating associated with sweating over the corresponding area. The blush involved the ear, which, however, did not perspire. Mere masticatory movements did not produce the blush, but putting vinegar into the mouth without moving the jaws brought it out. The patient had formerly a suppurating gland behind the ear, and Dr. Weber presumed that some of the vaso-constrictor branches of the cervical

Digitized by Google

sympathetic were involved in the scar, so that when the parotid gland became distended under the stimulus of mastication it dragged upon or compressed these branches.

Mr. L. A. DUNN showed a man, fifty years of age, on whom he had performed Pylorectomy for Cancer of the Pylorus. He was admitted with an enormously distended stomach, and on palpation a tumour was felt in the region of the pylorus. On cutting down a growth the size of a small orange, which was quite free, was found and removed, and then, closing the divided end of the stomach, a communication was established with the duodenum by the aid of a Murphy's button. This was passed without difficulty on the eighteenth day, and the patient recovered without giving them any anxiety. He had since gained three stones in weight, and was apparently in perfect health.

Mr. ABBOTT showed a lad, sixteen years of age, a patient under the care of Mr. Clutton, suffering from Symmetrical Coxa Vara. He presented nothing peculiar in his gait until about a year ago, when, a few days after a fall from a van which did not give rise to any obvious pain or injury at the time, he began to experience some difficulty in walking. The stiffness in the hips had increased so that in the course of three months he had to give up work. He now only complained of stiffness, and he walked with a kind of waddle, with everted knees. There was symmetrical eversion of the lower limbs, with great limitation of inversion, flexion, and especially of abduction, while adduction had remained quite free. The great trochanter was not above Nélaton's line. There were no creaking in the joints, no osteophytic growths, and no pain on palpation or movement. Skiagraphs showed that there was shortening of the neck of the femur. He regarded it as a case of coxa vara coming on in adolescence.—Mr. MAKINS observed that in genu valgum of adolescents the bone was usually very soft and largely decalcified.

HARVEIAN SOCIETY OF LONDON.

The Use of Large Doses of Creosote in Phthisis.—Unusually Large Tuberculous Glands.—Varicose Veins in Both Legs complicated with Eczema.—Arthritis.—"Massage Chain."

A MEETING of this society was held on Oct. 21st, Dr. MILSON, the President, being in the chair.

Dr. CLIFFORD BEALE read a paper on Recent Experience of the Use of Large Doses of Creosote in Consumptive Cases, and gave an account of a series of cases of incipient tuberculous disease of the lung and another series of the more chronic forms of disease. The patients had been treated with doses of pure beechwood creosote dissolved in cod-liver oil, beginning with three or five minims, the same amount being added to the previous dose every alternate day until a maximum of 180 or 160 minims per diem was reached. He had found that of all the methods of giving the drug this appeared to be the least objectionable to the patient. The results achieved had been highly satisfactory and in some cases most striking, the most marked effects being produced when the larger range of dose was reached. The fall in temperature, gain of weight, and general subsidence of symptoms had in many instances been surprising, and seemed to be more definite and lasting than the degree of improvement commonly observed as the result of hygienic treatment only. Contrary to expectation, no complaint was made by the large majority of the patients of the smell of the drug, and it was probable, both from clinical observation and chemical experiment, that the creosote was very rapidly broken up in the stomach, possibly forming a more stable compound, in which form it was excreted very freely and rapidly by the kidneys. Its presence could only be detected in the urine after further distillation with strong sulphuric acid. In many instances the patients passed blackened or greenish urine, but it could not be ascertained that either the quantity or chemical composition of the urine was otherwise materially altered, and there were no unpleasant symptoms attending the altered colour of the excretion. Further chemical investigation was, however, necessary to explain some of the changes which the drug undergoes in the body. As a result of purely empirical use it appeared that an amount of success was to be obtained by its employment, especially in the early cases, which was quite equal to, if not better than, the results obtained by the more specialised preparations such as guaiacol and its carbonate, and it was evident that it could be well tolerated when dissolved in cod-liver oil, and hence the painful and unpleasant methods of introduction, such as subcutaneous or rectal or tracheal injection, were rendered unnecessary. The drug was not to be regarded as in any sense a specific remedy for the disease, but rather as a valuable adjunct to the many existing methods of hygienic treatment at present in use.—Dr. ST. CLAIR THOMSON said that his personal experience was limited, and if he were to quote it it would doubtless show that every patient who had recovered or improved had taken creosote. But whether such patients recovered because they were taking creosote, or in spite of having had that drug prescribed, would be a very difficult question to answer. However, he was able to quote the much more valuable experiences which he had heard of this summer when visiting the well-known sanatorium for phthisical patients founded by Dr. Dettweiler at Falkenstein in the Taunus Mountains. The patients in this institution belonged to the well-to-do classes, and the resident physicians had most exceptional opportunities for observing the effect of any drug. Creosote had there been given a thorough trial, and had now been completely abandoned along with tuberculin and all other specific remedies. Small doses were occasionally given, but merely for their effect on the digestive system. Treatment at Falkenstein was entirely symptomatic, and general dietetic and hygienic influences were the only remedies relied on. He suggested that in Dr. Beale's cases the improvement might be due to the rest and good food which the patients obtained in the well-ventilated wards of a chest hospital. Before attributing any virtue to the creosote it would be necessary to see the results obtained in an equal number of similar cases, treated in exactly the same way, but with the creosote omitted.—Dr. STAMFORD G. FELCE inquired whether Dr. Clifford Beale used creosote of any particular manufacture, as he had found the results vary greatly with different specimens of the drug, which, though occasionally well borne, was in a large percentage of cases not tolerated by the stomach. As commercial creosote is a more or less variable mixture, containing toxic cresols, paracresols, and pyrogallol, it seemed to him more rational to use a drug which, possessing equal efficiency, is of a definite chemical constitution—a condition that is fulfilled by guaiacol carbonate; in a fairly large series of phthisical patients he had found this drug well tolerated, and in suitable cases frequently beneficial.—Dr. WILLIAM SQUIRE, Dr. CLEVELAND, and others also took part in the debate.

Mr. EDGAR G. BULLEID showed a case of Unusually Large Tuberculous Glands removed by him from the Right Axilla in a young man, aged twenty-three years.

Dr. ALFRED EDDOWES showed a case of Varicose Veins in Both Legs complicated with Eczema. The patient, a young man, had had several veins excised a few years ago at King's College Hospital with little or no benefit. Dr. Eddowes therefore wished to know whether surgeons had found excision of such veins so generally satisfactory as to justify him in urging this patient to submit to further operation, notwithstanding the first disappointment. If those present could not hold out good hopes of success he intended to adopt a plan of his own which had given him good results. Having cured the eczema—an easy matter in this case—he would cleanse the skin, dust it over with a permanent antiseptic such as calomel, and apply well-fitting elastic stockings, to be worn night and day for two or three months without intermission.

Dr. KNOWSLEY SIBLEY showed a case of Arthritis in a man, fifty-nine years of age, who had been sent to him at the North-West London Hospital by Dr. Macevoy for the Tallerman hot-air treatment. As a small child the patient suffered from scrofulous disease of both hip-joints, which had left scars from healed sinuses over both greater trochanters. When seven years old he went to work in a brickfield and was able to run and jump as well as any boy of his age. He continued at heavy labourer's work until last spring, when he found his hips were becoming stiff and he was unable to bend down as formerly. He was soon compelled to give up work and had been getting gradually worse ever since. At the present time the patient had little or no pain, but he could only just raise his feet from the ground; he walked with his back bent forward from the lumbar region, and was unable to cross his legs when sitting down. He had had only three baths and said that his movements were already much freer and he was able to get about better.

Dr. SIBLEY also showed a new apparatus known as a "Massage Chain," which had been sent to him by a friend

Digitized by Google

in Germany some six months ago, and he had given it a trial at the hospital. The chain consisted of a series of small revolving wooden balls with a handle at either end. It was used by holding one handle in each hand and giving a to-and-fro movement over any part of the body to which it was desirous to apply massage.

OPHTHALMOLOGICAL SOCIETY.

Some Experiments on the Union of Corneal Wounds.—Dislocation of Lens; Couching; Recovery.—Exhibition of Specimens.

THE first general meeting of this society for the present session was held on Oct. 21st, Mr. H. R. SWANZY, President being in the chair.

After thanking the society for the honour conferred upon him in his election to the Presidency, Mr. SWANZY proceeded to consider some Congenital Cases of Disturbed Association of Muscular Action, Coloboma, and Microcephalus with Proptosis, the last being illustrated by lantern slides.

Mr. ERNEST CLARKE related the results of some Experiments on the Union of Corneal Wounds, consisting of various operations on the cornea of rabbits whereby the anterior chamber was completely emptied of aqueous with the view of ascertaining the time taken by these wounds in uniting sufficiently to allow the anterior chamber to be re-formed. Descriptions of the methods adopted in operating and preserving the specimens were given. Two classes of experiments were performed. In the first class the animal was kept under an anæsthetic and killed. The anterior chamber was found to be present in two minutes, and fully re-formed in twenty-five minutes. In the second class the animal was allowed to recover and, after varying intervals, ranging from half an hour to two and a half hours, again placed under an anæsthetic and killed. The movements of the animal caused delay in the re-formation of the anterior chamber. The average time was one and a half hours. Wounds at the upper margin united most rapidly with less scar. Wounds across the centre of the cornea and at the lower margin took longer to repair and made a larger scar. The rapidity with which the anterior chamber was re-formed suggested that, if during an operation on the eye where the presence of the aqueous was necessary, this aqueous were accidentally lost, the eye should be bandaged and the continuance of the operation postponed only for half an hour at the outside, instead of postponing it until the next day as was generally done. The experiments also showed the great influence that rest had on the process of repair, and emphasised the importance of keeping patients absolutely quiet for the first few hours after an eye operation. The PRESIDENT, commenting on the value of these experiments, said that their interest would have been still further increased if it could have been determined how soon a wound in the cornea, which had undergone primary adhesion, became impervious to the entrance of infective organisms.—In reply to questions by Dr. ARGYLL-ROBERTSON, Dr. BATTEN, Mr. P. SMITH, and Mr D. MARSHALL, Mr. CLARKE said that the size of the wound was that of a full-sized keratome, 4 to 6 mm.; the eyes were looked at within a few minutes of the incision and conjunctival flaps had been avoided in order not to complicate the experiments.

Mr. T. H. BICKERTON related a case of Congenitally Misplaced Lenses, which became dislocated spontaneously into the anterior chamber. Couching was followed by recovery of perfect vision. The patient was a male, aged twenty-eight years. He had been short-sighted since infancy; at fourteen years of age he had attacks of giddiness, which caused him to fall and injure his forehead. At the age of nineteen years he began glasses: R—6·5 D., L.—6 D He was first seen in December, 1887. At that time the iris was tremulous; the lens was dislocated into the vitreous in each eye: V. R c. +10 D. = $\frac{6}{6}$; L.c +10 D. = $\frac{6}{24}$. On reading the refraction was entirely different: J. 1 at 3½—4 in.; he looked through the displaced lens. In 1893 he suddenly went blind in the left eye, but the vision was restored next morning. He had two more attacks of the same nature afterwards; during the last one eserine was used, and the eye did not recover as it had previously done. When seen after this occurrence in December, 1893, there were pain and congestion and the clear lens nearly filled the anterior chamber. The unsatisfactory results obtained from extracting such lenses and the knowledge that these lenses had been tolerated so long in the vitreous suggested to Mr. Bickerton the alternative of reposition. On Dec. 30th, 1893, this was done; the pupil was dilated, an incision at the margin of the cornea was made with a keratome, to evacuate the aqueous it was attempted to press the lens back through the pupil by the finger applied to the closed lid; this could not be done and a spatula was introduced into the anterior chamber; the lens then slipped back into the vitreous. Perfect recovery followed, and in June, 1897, three years later, the vision of the eyes was R c. + 12 D $\frac{6}{5}$ ptly, $\frac{\text{L.c} + 12\text{Ds.}}{-75\text{ D cyl.}} = \frac{6}{5}$. The interest of the case lay in the fact that blindness followed the use of eserine, which prevented the lens from passing back again into the vitreous, and the fact that the eyes have remained perfectly healthy, although the lenses had been dislocated into the vitreous for nearly four years.

The following cases and card specimens were shown:—

Mr. ADAMS FROST: Odell and Porter's Centreing Instrument for Ophthalmic Lenses.

Mr. ARNOLD LAWSON: Leuco-sarcoma of the Choroid.

Dr. RAYNER BATTEN: (1) Foreign Body found Impacted on the Optic Disc after Removal of Traumatic Cataract; (2) Pulsating Tumour of the Orbit, ? Meningocele.

Mr. J F. BULLAR: Case of Deficiency of the Choroid.

Mr. LANG: Primary Syphilitic Lesion of the Inner Canthus.

LIVERPOOL MEDICAL INSTITUTION.

Ileum Strangulated by Passage through a Congenital Mesenteric Hole—Excision of the Kidney for Primary Carcinoma.—The Typhoid Serum Reaction in Doubtful Cases of Fever.—Clinical and Statistical Evidence of the Value of Antitoxin in the Treatment of Diphtheria.

A MEETING of this society was held on Oct. 21st, Dr. RICHARD CATON, President, being in the chair.

Mr. STANLEY KELLETT SMITH related a case of Ileum Strangulated by Passage through a Congenital Mesenteric Hole, an account of which is published elsewhere in our present issue.

Mr THELWALL THOMAS related a case of Excision of the Kidney for Primary Carcinoma. He exhibited a patient from whom he had removed the right kidney for primary carcinoma. The man, aged thirty-nine years, said that his urine had been coffee-coloured two years ago. Occasional attacks of hæmaturia occurred in the last twelve months and he steadily lost weight. A month ago he fell, striking his right side. He immediately passed half-a-pint of bloody urine and clots; after this he passed no urine for three days. His temperature oscillated, suggesting suppuration. The tumour was large and occupied the kidney area and the right iliac fossa. Operation was performed as follows. A transverse incision immediately under the last rib was made, exposing the kidney, and rapidly enlarged forwards, peeling the peritoneum off the kidney. The tumour, which weighed 2 lb. 2 oz., was removed. The microscope showed a carcinoma with large cells, as seen in suprarenal rests. The patient had gained about 2 st. in weight since the operation.—Dr. E. T. DAVIES remarked that by the transperitoneal incision it is possible to examine the condition of the other kidney, which was a matter of the greatest importance.—Mr. F. T. PAUL said the microscopical characters of the tumour were those usually observed when cancer commenced in the glandular structure of the kidney. He thought the character of the cells, their arrangement, and the presence of cysts pointed to origin in the true renal tissue rather than in adrenal rests.

Mr. RUSHTON PARKER related a case of Carcinoma of the Kidney where he removed the kidney, the patient making an easy recovery; recurrence occured, however, in about two months.—Dr. ALEXANDER also made some remarks.

Dr. CARVER read a note on the Typhoid Serum Reaction in Doubtful Cases of Fever. He related two cases of fever; both were thought, when first seen, to be cases of typhoid fever, the serum in each giving, with a solution of 1 to 30, a markedly positive reaction with Widal's test. Yet both terminated on the sixth and eighth day respectively in recovery. The results must show either, as he believed, that we must enlarge our conceptions of typhoid fever or that the test was applicable to other febrile conditions. In another case there was no reaction on the seventh day, but a marked one on

Digitized by Google

the ninth after the introduction of typhoid antitoxin. Yet the serum of a patient suffering from appendicitis into whom a similar dose of typhoid antitoxin had been injected was entirely negative in its reaction, as was also Dr. Carter's own blood when mixed out of the body with a small proportion of the antitoxin and diluted.—Professor BOYCE said that the vast majority of cases of typhoid fever give the reaction. There were two important questions: (1) Does absence of reaction preclude typhoid fever? and (2) does a positive indication always signify typhoid fever? In answering the first question he mentioned (1) retarded reaction; (2) one or two cases of typhoid fever have given reaction when the absence of the typhoid bacillus has been proved; and (3) absence of reaction has been justified by necropsies. The answer to the second question is an almost unqualified affirmative.—Dr. N. E. ROBERTS said that it was disappointing to the physician to come across cases where the serum test did not answer. He had four such cases at present in the wards of the City Hospital. Three were undoubtedly typhoid fever, and he believed the fourth was, yet the result of the serum test was entirely negative. In the large majority of cases, however, the results were highly satisfactory and the test a valuable acquisition.—Dr CATON, Dr. BARR, and Dr. STANLEY GILL also discussed the subject.

Dr. E. P. MANBY read a paper on Some Clinical and Statistical Evidence of the Value of Antitoxin in the Treatment of Diphtheria. He had tabulated about 10,000 cases which had been treated at the Metropolitan Asylums Board Hospitals. He drew attention to the early experiments of Behring and Wernicke with antitoxins, and quoted from Roux's paper on the antitoxic treatment of diphtheria at the Budapest Congress He then mentioned the introduction of the treatment into the metropolitan hospitals, and drew attention to the death-rate before and after the introduction of the antitoxin. He then discussed the question of dosage, and drew attention to the fact that the amount of the antitoxin to be used must be gauged by the severity of the disease and not by the size or age of the patient. He then mentioned how the ordinary course of the disease was modified and how the sufferings were mitigated by the antitoxin injections. He also mentioned the dangers of the injections themselves. The statistical examination of the subject was highly favourable to the treatment.—Dr. N. E. ROBERTS remarked on the relatively small number of cases of diphtheria in Liverpool hospitals as compared to London. He agreed that the serum treatment had reduced the mortality, especially in laryngeal cases. His figures, although too small to be of much value, supported Dr. Manby's views.—Dr. HOPE attached greater importance to careful observation than to deductions drawn from statistics. Although, happily, diphtheria was relatively much less prevalent in Liverpool than in London, the Hospitals Committee of the City Council had made provision for a gratuitous supply of diphtheria antitoxin.—Dr. CARTER, Dr. HUGH JONES, Dr. MACALISTER, Dr. PERMEWAN, Mr. BLAKEMAN, Dr. P. DAVIDSON, and Dr. LOGAN joined in the discussion.—Dr. MANBY replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

President's Address.—Exhibition of Cases and Specimens.—Injuries Produced by Cycling.—Treatment of Surgical Tuberculosis.

THE opening meeting of this society was held at the General Infirmary, Leeds, on Oct. 15th, Dr. BRAITHWAITE, President, being in the chair.

The PRESIDENT read a paper entitled "Is there any Principle or are there any Principles, Scientific or Practical, in the Treatment of Disease?"

Mr. STOTT showed a woman who on six occasions had been Exposed for about forty minutes to the X Rays for the Diagnosis of Spinal Caries. Two days after the last exposure severe pain occurred over the sternum followed in eight days by a circular ulcer six inches in diameter. In seven months this had lessened to an area three inches by two inches, and this Mr. Stott had successfully treated by two plastic operations.

Mr. W. H. BROWN showed: (1) A case of Paraplegia following Spinal Caries; laminectomy; (2) Amputation through the Hip joint for Sarcoma; and (3) Aneurysm of the Femoral Artery after Ligature of the External Iliac.

Dr. TREVELYAN showed a Hand Centritugal Machine for obtaining Deposits for Microscopical Examinations, with Specimens.

Mr. KNAGGS exhibited specimens from two cases of Excision of the Knee, Tuberculous and Osteo-arthritic.

Dr. HELLIER showed Secundines and Fœtus from a case of Triple Pregnancy.

Dr. WARDROP GRIFFITH showed: (1) Large Cerebral Hæmorrhage from a patient who presented General Atheroma with Cardiac Hypertrophy and Evidence of Old Embolism of the Kidneys; the kidneys were not granular (Dr. Barr's patient); and (2) Specimen of Communication between the Hepatic Flexure of the Colon and Second Part of the Duodenum from Malignant Disease of the Former. The symptoms were those of collapse and fæcal vomiting without distension of the abdomen and typhlotomy was performed (Mr. Robson's patient).

Mr. E O. CROFT showed a case of Recovery with Movable Joint after Incision of the Knee for Acute Suppurative Arthritis.

Dr. CHURTON showed a specimen of a Tumour of the Middle Lobe of the Cerebellum and read notes of the case. In July or August, 1896, a child, two and a half years of age, a member of a delicate and tuberculous family, vomited, staggered, and in a few days became unable to walk. She soon became nearly blind, but the pupil reflexes remained. The arms were not at first affected. She was admitted into the Leeds Infirmary on May 26th, 1897. The head had enlarged recently. No hemiopia had been observed; there was no pyrexia; no disease was found in the other organs; and there was no wasting of the limbs. The child was usually very quiet, but at times fretful. There was double optic neuritis. On April 7th the right face and arm were almost icy cold; the left was of normal temperature. On April 13th the right face was flushed and hot; the left was pale and cold. Vaso motor reflexes were not distinctive. The legs were rigidly extended; at times she drew up the left thigh and bent the knee, the foot being still extended. She never drew up the right knee. Plantar reflexes were present, the right being greater than the left. There was no ankle-clonus. Patella reflexes were present. Vesical and rectal reflexes were normal; she gave no notice of either being about to act. On June 26th the fontanelles and sutures were reopened; the posterior fossa (occiput) greatly bulged towards the neck, but the frontal region was not enlarged. There was general hyperæsthesia at times, also there were frequent cries and screams as if from paroxysms of pain. Exalgine appeared to prevent those paroxysms for a few hours. On June 28th the thumbs were drawn across the palms, the fingers were flexed, the legs were hyper-extended, the knees were locked, the legs were spread out each to an angle of 25° with the thigh (apparently by action of the outer hamstring muscles), and the left thigh was turned outwards by a rigid tensor fasciæ femoris. On July 9th the right lateral ventricle was tapped through the sagittal suture; 1½ oz of clear fluid were drawn off. Tapping was repeated on July 13th and 30th, and on Aug 9th and 16th, on return of the signs of pain. Complete relief always followed; but emaciation became very marked and death occurred early in September. A sarcoma as large as a Tangerine orange occupied the position of the middle lobe of the cerebellum, the upper part of the lobe formed a roof, while the lateral lobes appeared like easily separable encysting walls for the growth. Chronic tuberculous disease was found in some of the mesenteric glands.

Mr. LITTLEWOOD showed a boy, aged five years, upon whom he had operated on June 12th for Acute Suppurative Arthritis of the Left Hip. An incision was made over the front of the joint and fifteen ounces of pus escaped. The head of the femur and acetabulum were quite devoid of cartilage. The joint was drained and dressed with iodoform. On Aug 12th the incisions were opened again as the joint was not draining well. The incisions had healed and the patient was walking about with an ankylosed hip.—Mr. LITTLEWOOD also showed a Hydatid Cyst with its investing Capsule, of about the size of a goose's egg, which he had removed from the edge of the left lobe of the liver of a woman aged forty-eight years. The cyst was adherent to the omentum and the anterior abdominal wall. Before operation it was thought to be a mass of malignant disease. The patient has made a good recovery.

Mr. W. H. BROWN read an interesting paper on Certain Injuries produced by Cycling and reported several cases where patients had suffered from pain around the anus, in

Digitized by Google

the testicles, and inner side of the thighs. In some cases there was extravasation of blood under the skin, in others the penis became insensitive and there was retention of urine. Most of the riders were of the male sex. Mr. Brown attributed the condition to the use of badly fitting saddles and advised would-be riders to pay attention to this most important part of the machine. All his patients recovered with rest and sedatives.

Mr. MAYO ROBSON read a paper on the Treatment of Surgical Tuberculosis, such as psoas abscess, tuberculous joints, tuberculous abscesses connected with the ribs, tuberculous disease of the vesiculæ seminales, &c., which he had been treating for a number of years by iodoform injections with very satisfactory results. He described the details of the methods he employed, and pointed out how in one class of cases—viz., tuberculous joints—operations at the Leeds Infirmary for excisions had fallen from sixty-three in 1891 to thirty-three in 1896, although a much larger number of cases had been treated. He attributed this change to the large number of cases that were now being successfully treated by iodoform injections. He dwelt on the great importance of strict asepsis in performing the operation, and remarked that even if no good were done no harm could follow; but according to his experience benefit had accrued in nearly every case, and in many cure had resulted.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimen.—President's Address.

THE first ordinary meeting of the session was held on Oct. 15th in the Medical Institution, Hope-street, Liverpool, the President, Dr. BRIGGS, being in the chair.

Dr. T. B. GRIMSDALE (Liverpool) showed a Uterus, with large, soft, rapidly growing fibroid, removed by abdominal hysterectomy.

The PRESIDENT delivered his inaugural address, the subject being "The Diagnosis of Cancer of the Uterus in its Early Stages." In his address Dr. Briggs dealt with the causes of delay in gynæcological and general practice in completing the diagnosis in cancer of the uterus. He observed that the argument of the senior gynæcologists against the introduction of vaginal hysterectomy into this country appeared to be still valid—viz., the difficulty in making a diagnosis in the early stages of uterine cancer. The mortality of operations has diminished, but the fact is still with us that the cancerous disease has advanced beyond the uterus before the radical operation is performed. The surgeon, he held, must deplore the haphazard methods of treatment, the attempts at cure by the curette before the diagnosis can be complete, and the consignment of curettings to the sink rather than to the pathological laboratory. The utility of the microscope cannot be seriously doubted except in a few of the adenomata; the ordinary carcinomata can be detected earlier by the microscopical than the clinical methods. By way of illustrating the address thirty micro-photographs of adenomata and carcinomata were shown by the lantern. The gradation in the structural characteristics between the malignant adenoma and the normal glands were shown. The corresponding clinical histories were related and in several instances years had elapsed; malignant cases had died; non-malignant cases had been tested by time. He drew attention to the one solitary stratified squamous carcinoma of the body of the uterus; similar cases had been described by others from time to time; then he pointed out in another carcinoma the gradation from glandular columnar cells to stratified squamous patches according to the cancerous alveoli. There seemed to be no good reason for retaining the term "adeno-carcinoma," which was often used for malignant adenoma and for ordinary carcinoma of glandular origin, and difficulties of comparison were introduced. Sections of glandular and papillary erosions in suspicious cases were also exhibited. Naked-eye water-colour drawings from the recent specimens showed in most instances advanced cancerous growths of the body of the uterus and of the cervix; two of the latter were examples of cancer, starting first below the internal os. One of the latter had been twice curetted and "villous" endometritis was believed to exist. In many other instances the curette had been used, but not for an exploratory purpose, which, from the point of view of all concerned, was to be regretted.—Dr. LLOYD-ROBERTS (Manchester) proposed, and Dr. MACFIE CAMPBELL (Liverpool) seconded, a vote of thanks to the President, which was carried with acclamation.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—The Value of Bacteriological Research in the Diagnosis of Infectious Disease.

THE opening meeting of this society was held on Oct. 3rd, the retiring President, Mr. GODFREY CARTER, being in the chair. After the election of officers—

Dr. EUBICH gave a Microscopical Demonstration.

Dr. GLADSTONE showed a case of Extensive Necrosis of the Cranial Bones, probably syphilitic in origin.

Mr. MCGEE related a case of Broncho-pneumonia which had pursued a very unusual course.

Dr. METCALFE showed a large Enterolith from a Horse.

Dr. CHAPMAN showed a specimen of Epithelioma of the Sigmoid Flexure. The case had presented itself as one of extensive abscess of the thigh pointing above the knee. When opened gas and fæcal pus escaped. The patient slowly sank and at the necropsy the condition exhibited was found.

After a vote of thanks to the retiring President, the President-elect, Dr. ARNOLD EVANS, took the chair and read a paper on the Value of Bacteriological Research in the Diagnosis of Infectious Disease, particularly in relation to Cholera, Typhoid Fever, and Diphtheria. Dr. Evans pointed out that some difficulty had been experienced as to the significance properly attaching to the results of bacteriological examination in the diagnosis of cholera, and expressed the opinion that, so far as at present known, Koch's comma bacillus was not found in the intestinal evacuation in any disease except cholera. It was therefore possible to decide by bacteriological examination whether any particular case was true cholera or not and to give a direct negative or affirmative opinion on the nature of any material examined. As to the assistance given by bacteriological examination in the diagnosis of typhoid fever, Dr. Evans observed that it was twofold—viz.: (1) the recognition of the Eberth-Gaffky bacillus in the bowel discharges: and (2) the effect produced by toxines contained in the body on the life and growth of cultures of the typhoid bacillus, as shown by Widal's reaction. He combated the view put forward some years previously that the bacillus coli communis could obtain under any conditions the pathogenic properties of the bacillus typhosus, and described the points of difference between the two organisms. After discussing the significance of the Klebs-Löffler bacillus in reference to diphtheria and other throat affections he showed a number of cultivations of microbes on agar and other media from the throats of patients suffering from whooping-cough, scarlet fever, croup, and enteric fever. The growths consisted of various kinds of micrococci, streptococci, and saccharomycetes.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

Presidential Address.—Annual Report.

THE annual meeting of this society was held on Oct. 13th in the medical library of University College, Bristol, Dr. J. E. SHAW being in the chair.

Dr. SHAW gave his presidential address on Some Points in Lunacy Practice in Relation to the General Practitioner. In the course of his address he remarked that the diagnosis of insanity is not a special or even medical process under the present state of our law, and that while every practitioner is now liable to be called upon to sign certificates there appears to be fairly adequate protection if the medical man is careful to act with due caution and with good faith. He thought that the present system of keeping lunatics of every mental grade in asylums led to an expenditure upon asylum buildings vastly in excess of what was necessary. He regretted that the present state of the law did not allow many classes of persons medically insane to be legally certified. He thought that it was desirable in accordance with the practice which obtained in Scotland that in this country also temporary certification should be made lawful,

Digitized by Google

and that hospitals for temporary retention should be established in the larger towns.

Mr. BUSH (honorary secretary) read his annual report, which showed a balance in hand of £108 8*s.* 1*d.*, with a membership of 134. He referred to the lamented death of Mr. Greig Smith and mentioned that a movement for providing a fitting memorial had been started to perpetuate his memory.

Dr. ROGERS (editorial secretary) read his report.

Mr. L. M. GRIFFITHS (honorary librarian) read his report which showed that in the Bristol Medical Library there were now 16,662 volumes and 206 current periodicals.

The following officers were then elected:—President-elect: Dr. Roxburgh, of Weston-super-Mare. Honorary Secretary: Mr. Paul Bush. Honorary Librarian: Mr. L. M. Griffiths. Members of Committee: Dr. J. Michell Clarke, Mr. J. Dacre, Mr. W. H. Harsant, Dr. Rogers, Mr. Munro Smith, and Dr. Waldo. Library Committee: Mr. Paul Bush, Mr. L. M. Griffiths, and Dr. G. Parker.

WORCESTERSHIRE MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Cystic Kidney.—Hyperpyrexia.

THE quarterly meeting of this society was held at the Worcester General Infirmary on Oct. 19th, Mr. T. BATES being in the chair.

Mr. BATES showed (1) a man whose Fractured Patella was treated by Immediate Wiring, the result being bony union of the fragments, with perfect movement of the joint; (2) a man with Severe Varix of both Internal Saphenous Veins as high as the knee; (3) a case of Lingual Tumour; (4) a child recently submitted to Tarsectomy for Talipes Equino Varus (before operation the patient was treading on the external malleolus and cuboid bone, but was now treading flat on the sole); and (5) a Multiple (uterine) Fibroid Tumour removed a few days previously.

Dr. COOKE showed (1) a specimen of Aneurysm of the Basilar Artery and (2) a specimen showing a Plum-stone impacted in each Bronchus immediately below the Tracheal Bifurcation. They were removed from a woman who had been seized with an epileptic fit whilst eating an apple. She suffered from intermittent dyspnœa for twenty-four hours, at the end of which time tracheotomy was performed, but without relief, and she died shortly afterwards.

Dr. READ gave outlines of a case of Cystic Kidney admitted under his care and subsequently transferred to Mr. Budd for operation.—Mr. BUDD, Mr. BATES, Dr. CROWE, and Dr. SMYTHE made remarks, and mentioned other interesting renal cases that had been under their care.

Dr. CROWE related a case of Hyperpyrexia of Probable Rheumatic Origin, in which the axillary temperature was 110° F. Cold packing was resorted to, with a resulting rapid decline of temperature to 100° in three hours. The patient lived for five days, gradually becoming comatose and dying at the end of that time.—Dr. POLLARD made some remarks, mentioning a case which had been under his care in which the axillary temperature was 108·2° Rubbing with lumps of ice brought the temperature down to 99°, and it sank half an hour later to 96·6°. The man eventually recovered.—Dr. STANLEY HAYNES asked whether any of the members of the society had tried phenocoll, with which he had seen some very good results in the pyrexia of influenza.—Dr. CROWE replied.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Inaugural Address by the President.

A MEETING of this society was held on Oct. 14th, Dr. SINCLAIR WHITE being in the chair.

After thanking the society for electing him to be president Dr. White gave an address on the Progress of British Surgery during the Victorian Reign. In the sixty years under review remarkable strides had been made in almost every branch of knowledge, and surgery had participated in the general advance to a greater extent perhaps than the majority of other arts and sciences. This was all the more gratifying because in no field had the incentives to the labourer been less selfish. When the Queen ascended the throne Liston and Syme were the rising stars of British surgery—the harbingers of a period of surgical activity which had lasted until now. The introduction of anæsthetics in "the forties" and of antiseptics in "the seventies" were the two most notable features of the period. The former extended enormously the field of surgery, but it was accompanied by at least one drawback. It deteriorated the standard of manipulative dexterity which had probably attained perfection in the early Victorian years, and opened the door to incompetent and bungling surgeons. Lister's discovery of antiseptics was without exception the most important in its results in the history of surgery. It substituted definite knowledge for dark mystery and revealed the character of "septic infection" the surgeon's ubiquitous and most dreaded foe. Step by step the methods of controlling sepsis had been simplified and perfected, and almost imperceptibly antisepticism had given place to asepticism which is now the aim of every intelligent surgeon. By reason of Lister's discovery surgical operations had assumed the nature of laboratory experiments, in the performance of which it was possible to control the conditions, and if failure resulted it would in nine cases out of ten be due to ignorance or, worse still, to neglect of well-known principles. The recent advances in surgery had been possible only because of Lister's work. Of these the more brilliant concerned the cerebro-spinal system, while for variety and the frequency with which they are performed abdominal operations still held the first place. Every region of the body had been diligently prospected by the surgeon and made to yield its tribute to his invincible energy. The vast majority of new operations had been of real service to suffering humanity, but occasionally, in Dr. White's opinion, surgical enterprise had over-reached the bounds of prudence.

Reviews and Notices of Books.

Heart Disease, with Especial Reference to Prognosis and Treatment. By Sir WILLIAM H. BROADBENT, Bart., M.D. Lond., F.R.C.P. Lond., F.R.S., and JOHN F. H. BROADBENT, M.A., M.D.Oxon., M.R.C.P.Lond. London: Baillière, Tindall, and Cox. 1897. Price 10*s.* 6*d.*

THE study of cardiac disease has always had much attraction for the physician. The reason of this is not far to seek; it is bound up with the important office which this organ fills as the centre of the circulation, and the far-reaching results of derangements of its mechanism. As regards the heart itself, the field of observation, although confined within a small area, is so remarkably varied, and affords so much material of interest in the interpretation of signs, as well as in the correlation of lesions, that it is not surprising it should have been assiduously cultivated by so many skilled clinical observers. Gradually there has been built up a conception of the whole subject which for thoroughness and accuracy occupies a foremost position in scientific medicine. This result has been attained in large measure by the careful comparison of the signs manifested during life with the lesions observed after death, together with that of the facts of the normal action of the organ. Yet interesting or even fascinating as the study of valvular lesions is from the point of view of auscultation, the capacity for correctly making a differential diagnosis of such defects is only one part, and perhaps not the most important part, of the physician's aim. He has to determine the extent to which the heart muscle has been affected by the derangement of the valves, and to ascertain from the observation of secondary changes in other organs the amount of actual disturbance of the circulation that has been set up, so that some indication can be obtained as to the means best adapted to restore to the organ that compensatory power which happily it seems to possess in an eminent degree. Much has been done to increase our knowledge of cardiac diseases in every direction, and although from the nature of

Digitized by Google

their clinical study the field of facts has often been obscured by the mists of speculation, it is not too much to say that our vision has been made clearer and our deductions sounder by the labours of the many who have studied the subject from every point of view. There are still obscurities in the sphere of etiology, but in the matter of diagnosis we seem almost to have attained the possible limit, whilst in respect to prognosis the views of physicians have become remarkably modified through more rational and more exact inferences upon the precise extent of mechanical derangement that is presented. Finally, as regards treatment there is at the present day much more confidence than was possible at a time when the conditions of the circulation in heart disease were less well understood and the compensatory powers of the damaged organ less fully appreciated.

Amongst those who have contributed largely in our own day to the promulgation of rational views on this subject Sir W. Broadbent occupies an honoured place. The attention which he has paid to the clinical study of cardiac affections, and the wide experience which one in his position cannot fail to have gained, pre-eminently qualify him to speak with authority on the subject. The work before us—in the preparation of which he has been aided by his son, Dr. J F. H. Broadbent—will therefore be certain of a cordial welcome; and we venture to add that this will be all the more cordial when it is found that the authors have not attempted to write an encyclopædic treatise on the subject, but have rather contented themselves with dealing with it from the strictly practical and clinical standpoint. There is indeed one notable feature in the book which deserves especial commendation, and that is the thoroughly reasonable manner in which the phenomena are interpreted, and that, too, in the fewest possible words There are no elaborate disquisitions upon the precise significance of this or that sign, but a plain, straightforward acceptance of the view which seems to be most in accordance with the dictates of common-sense. It is this quality in the book which will render it very acceptable both to practitioners and students, for it constitutes the best kind of teaching—that which is definite and rational. The first chapter briefly describes the anatomical relations of the heart and the methods of its clinical examination with the signs revealed by them are tersely stated. The subject of valvular disease in general is then discussed in several chapters, and also that of their treatment. Then come more detailed descriptions of each individual valvular lesion; and chapters on congenital malformations, adherent pericardium, structural disease (hypertrophy and dilatation) of the heart wall, fatty degeneration, angina pectoris, and functional affections (so-called) of the heart. In an appendix is given a note on the Preparation of the Baths and on the Movements Practised in the Schott Treatment of Heart Disease.

Without attempting to traverse the whole ground covered by the authors, it may yet be of interest if we briefly notice some of the salient points in the work. In the first place, we would concur with the opinion that simple aortic stenosis is the least common of the four valvular defects of the left side, although aortic systolic murmurs due to conditions which are not accompanied by stenosis are relatively frequent. The observation that the loudness of a valvular bruit is often inversely as the amount of the lesion is one which is worth remembering; it is especially well exemplified in mitral stenosis. Another indication of the extent of the valve-lesion which is here pointed out is the persistence or not of the normal heart sound. This fact, the importance of which cannot be gainsaid, is illustrated in cases of aortic incompetence, when the persistence of an audible second sound in the carotid tends to diminish the sense of the gravity of a lesion inferred by a loud diastolic murmur in the aortic area. The accentuation of the pulmonary second sound indicating hypertrophy of the right ventricle points to the severity of a mitral lesion; and the view that reduplication of sounds is due to asynchronism[1] of the two sides of the heart is adopted by the authors without reserve. The characters of the radial pulse in each form of valvular defect are clearly described and illustrated by sphygmograms, and the cause of the irregularity of the pulse in mitral incompetence is fully discussed in the chapter dealing with that affection, where it is shown to be probably due to the varying intrathoracic pressure due to inspiration and expiration influencing the amount of regurgitation into the auricle. In discussing the symptoms of mitral and aortic disease in general the causation of dropsy receives considerable attention. Whilst admitting the possibility of such factors as capillary deterioration and anæmic state of blood the authors clearly think that the mechanical view is sufficient to explain cardiac dropsy, and that the reason why dropsy is comparatively infrequent in cases of mitral stenosis is that the pressure on the arterial side is so much diminished in that affection as not to give rise to effusion of serum. The etiology of valvular diseases is fully discussed, and with respect to mitral regurgitation attention is drawn to the enfeeblement of the constricting muscle at the orifice of the valve as a factor in its production. Upon prognosis much valuable instruction is given both in the general section and in those chapters which treat of each of the individual lesions. Some highly interesting experiences are given as to the duration of life with valvular lesions, and the various circumstances that have to be considered in forecasting the prospects of longevity. The subject of treatment is judiciously dealt with and the value of exercise in cases of less severe lesions pointed out. Naturally, the lines of treatment introduced by Oertel and by Schott here fall to be considered. But in cases where there is failure of compensation to a severe extent stimulants may be needed and are of value; and there are some highly sensible remarks upon the indications for digitalis and other cardiac tonics. Having given a general survey of the subject of valvular disease the individual lesions are considered. Nor must it be thought that this is redundant. There are many points of great clinical interest discussed which will well repay perusal and careful study. We may just refer to one, and that is the occasional occurrence of a presystolic murmur in cases of aortic incompetence without mitral stenosis—"Austin Flint's murmur," as it is sometimes called. It is here suggested to be caused either by the vibration of the mitral cusp from the impact of the regurgitant eddy, or by this latter causing so complete a backward displacement of the cusp as to give rise to veritable mitral obstruction. The subject of mitral stenosis is treated with perspicuity, and the three stages or degrees of the lesion which can be clinically marked are well indicated. We would fain dwell more in detail on these and many other chapters of this most interesting work, but we have no doubt that it will be widely read and that it will be found most helpful, as well as satisfying, to its readers.

Lectures on Physiology: First Series on Animal Electricity. By AUGUSTUS D. WALLER, M.D. Aberd., F.R.S. London: Longmans, Green, and Co. 1897. Pp. 144. Price 5*s.* net.

DR. WALLER is the Fullerian Professor of Physiology at the Royal Institution, Albemarle-street, and a part of his duty is to deliver a course of twelve lectures on Physiology in the course of each year. This first series of lectures is a condensation of the twelve lectures he delivered as his first course. In his preface he feelingly deplores the few

[1] Since the issue of the work the publishers have drawn our attention to an erratum on p. 24, line 17, where the word "asynchronous" is printed "a synchronous," which the reader will at once perceive from the context to be an error.

Digitized by Google

and small advances that have been made in physiology by the previous holders of the chair, notwithstanding it has been occupied by men of high scientific attainments, and he attributes this failure to the circumstance that there is neither laboratory nor apparatus at the institution, nor does it "possess even one small room to keep itself alive," which is in remarkable contrast with the great advances that have been made in the other Fullerian professorship—that of chemistry and physics—by such men as Davy and Faraday and Tyndall, who have had command of a splendidly furnished laboratory and have been supplied with every means of furthering research. The first lecture is devoted to the demonstration of nerve and muscle currents, and Dr. Waller proposes two new terms—"zincative" to represent injured or active protoplasm, which is electro-positive; and "zincable" for resting electro-negative protoplasm. The second lecture commences with a description of some terms and of some instruments, and gives the results of the exposure of a nerve to carbon dioxide, to alcohol, and to tobacco smoke. He shows that nerve tissue is highly sensitive to the presence of carbon dioxide, which is not only a product of nerve action, but certainly facilitates nerve activity. In the fourth, fifth, and sixth lectures the effects of polarising currents are considered with an endeavour to render intelligible the phenomena of an- and cath-electrotonus. The lectures contain many facts of considerable interest, and they are not rendered less interesting by the author's acknowledgment of the difficulties he has met with in the preparation of the experiments and of his inability to explain some of the phenomena which he exhibits. It is satisfactory to think that the education of the Royal Institution audiences has risen to the height of enjoying lectures on so recondite a subject.

A Manual of Anatomy By IRVING S. HAYNES, Ph.B., M.D., Adjunct Professor of Anatomy in the Medical Department of the New York University, &c. With 134 half-tone Illustrations and 42 Diagrams. London: Henry Kimpton. 1896. Pp. 680. Price 12*s.* net.

THIS book is a manual of practical anatomy and deals with the structures of the several regions of the body in the order in which they are met with in dissection. The author tells us in his preface that "descriptions of the bones and the joints and of those minute parts which require special preparation for their dissection have intentionally been omitted." It has always been customary to omit from handbooks of practical anatomy descriptions of the bones, for these should have been learned before the commencement of dissecting, but the case is far otherwise with the joints. They should certainly be studied in connexion with the dissected part, for in no other way can the ligaments and the movements of the bones in a joint be understood thoroughly; therefore we cannot but look upon the omission of an account of the joints as a distinct drawback. The descriptions of the various structures met with are decidedly brief, but in a work on practical anatomy this is an error on the right side. As to the illustrations, which are numerous, it is obvious that the author has spent a great deal of trouble in preparing careful dissections and in taking photographs of these; from the photographs the majority of the illustrations have been prepared, and some are moderately successful, and give a very fair idea of the parts, but unfortunately many of the illustrations show very little; for instance, in Fig. 4, which represents a dissection of the side of the head, only the larger structures are discernible. The attempt has been most praiseworthy, but the results are lamentable. The diagrams are very good, and some composite photographs showing the relations of the viscera to the thoracic and abdominal walls are of great value. This form of composite photograph was brought forward by the author before the first Pan-American Medical Congress at Washington in 1893. The index is very copious, occupying more than thirty pages, and is exceedingly well-arranged and accurate.

LIBRARY TABLE.

L'Opération du Trépan. Par FÉLIX TERRIER, Professeur à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Bichat, et M. PÉRAIRE, ancien interne des Hôpitaux de Paris. Avec 222 figures dans le texte. (The Operation of Trephining. By FÉLIX TERRIER and M. PÉRAIRE.) Paris: F. Alcan. 1895 Pp. 283. Price 5 francs.—It cannot be denied that the authors of this work have treated the subject very thoroughly. They start with the trephining of prehistoric days as revealed to us by neolithic skulls exhibiting apertures made intentionally. When these skulls were first discovered it was thought that the openings were accidental or made after death, but their position, regularity, and the state of the bony margin sufficiently contradict these suppositions. The numerous instruments which have at various times been employed in this operation, and the changes which the operation itself has undergone, are very fully described. The second part deals with the methods of fixing the positions of the important cerebral convolutions and other intracranial structures such as the sinuses; and the third section is concerned with an account of the modern operation and the instruments used at the present day. It is certainly difficult to imagine that a more elaborate or complete work on the subject could be produced, and it is a monument of much hard work and careful research on the part of the authors. The illustrations have been supplied liberally and amount to more than 200 in number. Another point of excellence may be noticed; the references to original treatises on the subject are extremely numerous.

Transactions of the Eighteenth Annual Meeting of the American Laryngological Association, held in the City of Pittsburgh, Pa., in 1896. New York: D. Appleton and Company. 1897.—Many articles of great interest are contained in these transactions, but probably the most interesting refers to a case of fibro-chondroma of branchial origin, which was successfully removed from the pharynx of a child six weeks old by Dr. A. W. de Rosaldes; the tumour was covered with skin, containing hair follicles and sebaceous glands, and there was cartilage in its interior. Another paper of importance is one by Dr. C. H. Knight. It deals with the nasal sequelæ of syphilis and gives a good account of the employment of a platinum bridge for cases of necrosis of the septum; the illustration shows the marked improvement in appearance which may be obtained in some cases by this method of treatment.

Electro physiology. By W. BIEDERMANN, Professor of Physiology in Jena. Translated by FRANCES A. WELBY. London: Macmillan and Co. 1896. Demy 8vo. 17*s.* Vol. I.—To the advanced student of physiology the appearance of an English translation of Professor Biedermann's standard work will be welcome. The subjects dealt with in this volume are the structure of muscle, the phenomena of contraction, of electrical excitation and of electro-motive force in muscle, and the electro-motive action of epithelial and gland cells. We understand that the second volume may be expected shortly. The translation is well done and the style of the book is uniform with Professor Michael Foster's well-known "Physiology."

JOURNALS AND REVIEWS.

Scottish Medical and Surgical Journal.—Of the ten articles contained in the present number the most original is, perhaps, the one on Telegony, by Professor J. Cossar Ewart, of Edinburgh University. The word telegony was proposed by Weismann to denote the case in which

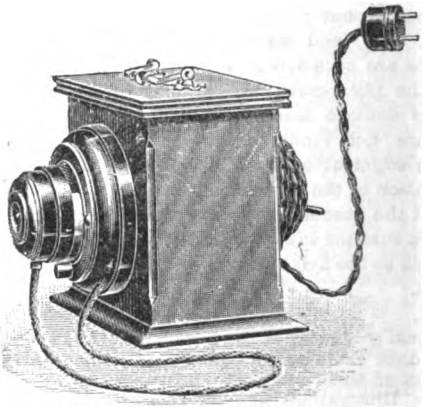
Digitized by Google

a female is so influenced by the first sire to which she bears offspring that the subsequent offspring to other sires present some of the characters or peculiarities of the first. Early in the century Lord Morton bred from a chestnut mare a quagga-hybrid, and the mare afterwards produced to a black Arabian horse a filly and a colt marked like the hybrid. In 1895 Professor Ewart formed a small stud and commenced various crossing experiments between horses and zebras. He now has five zebra mare hybrids, and the dam of a last year's hybrid has recently produced to an Arab horse a foal presenting numerous zebra-like stripes over the croup and loins. He enumerates the explanations of this phenomenon that have been suggested by Sir Everard Home, Herbert Spencer, and Weismann, all of which he thinks are highly improbable. An article of about twenty pages in length on Medical Education in Scotland gives full details of the curriculum in the Scottish universities and extra-mural schools.

Edinburgh Medical Journal.—Professor T. R. Fraser contributes the first part of a very interesting paper on Paroxysmal Hæmoglobinuria. The patient was a man between forty and fifty years of age who was under treatment in the Edinburgh Royal Infirmary in 1895 and again in 1897. The illness originated suddenly in 1889 from exposure to cold. The subsequent attacks were invariably due to the same cause, and they could be prevented even in the most inclement weather by the patient remaining in bed all day. With the patient's willing acquiescence several paroxysms were purposely induced by immersing the legs from the feet to the tubercles of the tibiæ for ten minutes in water at 45° F. During the attacks the colour of the urine varied at different times from red to black. Professor Fraser gives minutely detailed accounts of the condition of the urine, blood, circulation, &c. Mr. H. E. Durham, of the Pathological Laboratory, Cambridge, has a paper on the Serum Diagnosis of Enteric Fever, and also describes a modified form of Hæmocytometer. A special feature of this number is an article on Medical Education in the United Kingdom; it is about thirty pages in length, and gives a great variety of information useful to students.

Dublin Journal of Medical Science.—Mr. J. S. McArdle concludes his paper on the Treatment of Acute Intestinal Obstruction. Dr. Patrick Letters contributes the first portion of an article on Infantile Mortality in Ireland. He considers that the general public do not sufficiently appreciate the significance of infantile mortality regarded separately from mortality at all ages. He uses the term "infantile death-rate" to denote the proportion of deaths of infants under one year of age to births registered during the same period over which the deaths occur; it is expressed as so many per thousand births. Medical education and examinations in Ireland are very fully described in a chapter of about forty pages.

Friend of China.—This monthly, which is the journal of the Society for the Suppression of the Opium Trade, states that in fifty-eight years the Government of India derived from the opium traffic a revenue of £253,975,383, and adds that all this opium has gone to debauch the Chinese. This revenue, however, has greatly fallen of recent years, being this year only 5 per cent. of the total net revenue of India, whereas in 1883–84 it formed 19 per cent. of the revenue. A daily newspaper is quoted to the effect that in Johannesburg many Chinamen and Europeans do a thriving business by supplying Kaffirs with opium prepared for smoking.



Mercy and Truth.—An adventurous journey of several days' duration made by Dr. A. R. Cook is described by him under the heading of "A Medical Visit in Uganda." There are also portraits and short biographies of eight medical men, most of whom have recently left this country as missionaries.

New Inventions.

THE DIAMOND JUBILEE PORTABLE HOSPITAL TELEPHONE.

THIS ingenious instrument is the invention of the London and Provincial Telephone Company. It will be obvious to anyone that in cases of infectious disease it would be of great advantage to both the patient and other residents in the house if some communication could be kept up, so that during the long period of isolation, during which the patient may be perfectly well in other ways, he or she might not be cut off from all conversation. The instrument consists, as does any telephone, of a receiver and transmitter in addition to a case containing a battery, which are shown in the illustration (Fig. 1). Of course, two of these are required, one set placed in the sick room and the other in the room of the person to be communicated with. When the receiver is in place, as in

FIG. 1.

the illustration, it connects up the bell, the push of which is seen just underneath the receiver. When receiving a message the receiver is slid off the transmitter and held to the ear in the usual way. We have tested this instrument and found it to work admirably. As a practical instance of a case where this instrument would have been of great value we may mention the case reported in our columns last week where a medical man who was suffering from scarlet fever had to call his deputy into the room to give him instructions. Had he been possessed of a telephone of this kind all risk of infection would have been avoided. The price of the two instruments complete with twelve yards of wire cord is £4 10*s*

A similar telephone to the above, but without the case containing the battery and the flexible wire-cord, can be supplied to take the place of the ordinary electric bell-push in sitting- or bed-rooms, &c., for the sum of 36*s*. 6*d*. per pair. The existing bell, wires, and battery are left intact, and all that is required is to substitute one of the telephones (Fig. 2)

FIG. 2.

(which is not very unlike it in size and appearance) for the bell-push, connecting the bell-wire thereto, and the other to the bell or indicator in the servants' hall. This can easily be done by any local electric-bell fitter. Another neat form of instrument is made to stand on the writing-table if required. The advantage of having telephonic communication in conjunction with the ordinary electric-bells in private houses, hospitals, and other large establishments at so small a cost will be apparent to everyone. The instruments can be obtained from the London and Provincial Telephone Company, 11, Queen Victoria-street, E.C.

PLYMOUTH EYE INFIRMARY.—The Countess of Morley has promised to lay the foundation-stone of the new Plymouth Eye Infirmary on Dec. 1st. It is to be erected on a site near Mutley Railway Station.

THE LANCET.

LONDON: SATURDAY, OCTOBER 30, 1897.

A CONFERENCE on hospital reform, at the instigation of the Hospital Reform Association, was held in St. Martin's town-hall on Thursday, the 21st inst. The discussion was lively, and some new points were raised which will be seen in our report of the meeting on page 1137. One feature of the meeting was the presence of Sir WILLIAM BROADBENT, who displays an interest and an honest courage in dealing with this question which cannot fail to advance its ultimate solution. He spoke of hospital abuse as a great evil and an injury to the really poor.

The speech of Sir HENRY BURDETT is one to be noted by the medical profession. Sir HENRY BURDETT is not a medical man, but he poses so often as a semi-medical authority that his words become important on such questions. His remarks in explanation of the abuse of hospitals and on the remedies for curing them were alike noticeable. The common view of the profession as to the bloated proportions of the out-patient rooms is that the doors are opened too wide, that very indifferent inquiries as to fitness are made, that advice and medicines are given for nothing or next to nothing, and the crowding patients are led to believe that sooner or later, actually or potentially, the gratuitous advice and assistance which they will get are given by the heads of the profession. These great attractions are supplemented by stalls at which refreshments may be had on the same easy terms as the medicine. It is difficult for medical practitioners to compete with such terms as these. And Sir HENRY BURDETT might have found in this circumstance an explanation of the fact that whole classes, whose relief was never contemplated by the original founders of our hospital system take advantage of it. But, as if this were not enough, he must advance the theory that private practitioners are inefficient. This is really too much for the greatly enduring practitioners, who are first educated in the hospitals and then find themselves in sharp competition with them on such unequal terms. The profession might have expected more justice at the hands of one who professes to know so much about it. Has he any doubt that medical men could fill their consulting-rooms by the same methods that fill the out-patient rooms? Dr. WARD COUSINS happily and forcibly vindicated the medical profession, more highly educated and efficient than it ever was, from this unjust suggestion, as he had no difficulty in doing. But it will become a serious question, if these are really Sir HENRY BURDETT'S views, whether medical men should be asked to appear on the same platform with him again for the promotion of hospital reform.

A correspondent calls attention to another suggestion which seems to be equally dangerous. Sir HENRY BURDETT is enamoured of small subscriptions and small payments to hospitals, which seem to be associated in his mind with some claim on the part of those making them to medical attention at hospitals. The association of these things—a personal claim on hospitals for attention and assistance prior to that of poverty and sickness and apart from considerations of the social circumstances or the nature of the illness of those making petty periodical payments, is enough to transform hospitals from being the noblest institutions to being among the meanest, and to divert the streams of that public benevolence on which they must always depend. We shall be glad to hear that in this construction of his words we and our correspondent are wrong. But there is much in current events and in the abuse of hospitals which makes us fear that Sir HENRY BURDETT, with that happy conviction of his own insight into subjects which are not his proper study, is prepared to try experiments on our great hospitals and our great profession which are unwarrantable.

THE conclusions of the International Conference on Leprosy which has just finished its labours at Berlin will be read by medical men with considerable interest. Briefly stated these conclusions are: (1) that the leprosy bacillus (discovered by HANSEN in 1871) is the true cause of the disease; (2) man is the only animal in which that bacillus exists; (3) leprosy is contagious, but is not a hereditary disease; and (4) isolation of leprosy patients is desirable, and under such circumstances as exist in Norway compulsory isolation is to be recommended.

With regard to the bacteriology of the disease HANSEN'S researches from 1871 to 1874, followed by those of NEISSER in 1879 and afterwards by observers in various parts of the world, have fully established the fact recorded in the first of the above statements. For many years all efforts to cultivate the bacillus on artificial media failed. Quite recently, however, CAMPANA, of Rome, succeeded in obtaining cultures from cases actually progressing. This may account for the failures experienced by other observers, for most of their attempts have been made with material removed from advanced cases in which, according to CAMPANA, the bacilli have undergone degeneration.

The most important conclusions at which the Conference arrived, however, were as to the contagiousness of the disease and the methods to be adopted to check its prevalence. The Commission which investigated this subject in India in 1893 thought that the state of alarm occasioned by the report that leprosy was greatly on the increase was groundless, and urged cleanliness, strict observance of sanitary laws, improvement of general health, and variety of diet. Dr. HANSEN brought forward the following resolutions: 1. In countries where leprosy forms foci, or has a great tendency to increase, isolation furnishes the best means of preventing the spread of the disease. 2. The system of obligatory notification, observation, and isolation as carried out in Norway is recommended to all nations with local self-government and a sufficient number of physicians. 3. It must be left to the administrative authorities, after consultation with the medical authorities, to take such special measures as are applicable to the special conditions of the districts. Dr. PHINEAS ABRAHAM'S remarks on these points are especially interesting and will no doubt coincide with

Digitized by Google

the opinion of most of our English authorities. Our interest in leprosy is naturally concerned with its spread in India. Dr. ABRAHAM pointed out that where lepers are numerous and their friends still more numerous and not desirous of being separated from them harsh measures of isolation and segregation become impossible, their chief result being the concealment of cases. This has been well exemplified in the case of South Africa, where recent inquiries led to the conclusion that the attempts to send all lepers to Robben Island only resulted in many cases being hidden throughout the country. Many medical authorities of eminence (the speaker continued) strongly disapproved of stringent legislation, and until medical opinion became unanimous and our knowledge of the pathology and etiology of the disease more complete the question of legislation would continue to be decided according to the views of individual governments. This was especially true as regards the British Empire, where social and political conditions in the different colonies and dependencies differed widely from one another. If the Government had had serious difficulty in enforcing simple sanitary precautions in the case of such an acute and fatal malady as the plague in India how much more difficult would it be to insist upon harsh measures in the case of leprosy. The above *résumé* of Dr. ABRAHAM'S remarks we have taken from the *Times* of Oct. 18th, and, as already stated, we feel that his words will commend themselves to English medical men. The difficulties that would arise in applying isolation to our Indian subjects would be immense; but with our advanced knowledge of the bacteriological origin of the disease it behoves those who are concerned in the regulation of sanitary matters in India to pay the most minute attention to the recommendations of the Commission of 1893. The Government will doubtless have the verdict of the Berlin Conference brought to their notice and can hardly venture to altogether ignore it; but whether further investigation will be officially ordered and another report demanded we cannot venture to foretell. The delegates were all high authorities on the subject, and consequently their recommendations must be duly and carefully considered.

THE number of attacks of enteric fever in Maidstone had reached 1748 by the 27th inst., and thus this epidemic only finds one parallel in the modern sanitary history of this country. That parallel is the case of Worthing, where, during an epidemic period of seven months, from May to November, 1893, as many as 1411 attacks were recorded, and both in Maidstone and in Worthing the vehicle of the disease has been a public water-supply. It might be difficult to hold the Worthing Corporation directly responsible for the distribution of the enteric fever poison by means of their water-supply, because the infection that reached the water in that case was the result of accidentally meeting a fissure in the chalk during works carried out to improve, or at least augment, the water service. But after the event it became clear that the wells, sunk as they were in so fissured a stratum as the chalk, had become surrounded by houses, sewers, and drains, as the result of the extension of the town, to such an extent that the supply ought to have been looked on with suspicion. Anyhow, a terrible object-lesson was afforded of the results liable to ensue on the infection, whether as the result of neglect or by accident, of a public water-supply. So long as each house in a town or village had its own well, sunk in a polluted soil, so long was enteric fever fairly general and habitual in its incidence in this country; but we were as a rule spared the great and tragic outbursts which now at times ensue when the infection is allowed to get access to a public water service by means of which thousands of people almost simultaneously run risk of being infected. The later reports of the medical officer of the Local Government Board record epidemics which prove incontestably that the grossest and the most culpable neglect still prevails as regards a number of our public water-services, whether the supply is derived from springs, deep wells, gathering grounds, or streams; and we fear that at times the extent of the negligence and danger bears a definite relation either to the amount of pecuniary profit actually derived from the sale of the water to the public or to efforts made to render that profit greater. This is a state of affairs which has hitherto been all but ignored by Parliament in granting powers to water companies, whether municipal or private; and it is to be hoped that the attention which has been drawn to the subject by the Maidstone epidemic will lead to a much more careful watch than has usually been exercised over the powers and liabilities conferred and incurred in Bills as to public water-supplies.

We studiously avoid implying that blame attaches, whether here or there, in the case of the Maidstone water-service, because it is now announced that the Local Government Board will, if requested, hold a public inquiry into the matter. What this new inquiry will be we do not know, nor is it clear whether or not the official inquiry which has now for several weeks been carried out by Dr. THEODORE THOMSON, of the Medical Department of the Board, will be superseded, or whether two inquiries will go on together. But one thing is clear, that in fairness to the water company judgment as to their proceedings antecedent to the commencement of the epidemic must now be suspended. In one sense this is a misfortune, for the public cannot obviously be informed what is the official decision come to as to the cause or causes of the outbreak until the new inquiry has been held and concluded.

But on one matter we can speak freely, and that is that the visits of our Special Commissioner have shown that Maidstone is placed, by reason of antecedent neglect in its sanitary administration, in precisely that position which will probably make it most difficult to shake off an infection such as that of enteric fever, and that it behoves the town council not to lose an instant in trying to repair the errors of the past. Wherever there has been filth which has had access to the surface soil; wherever there are water-closets—so miscalled—which have no water laid on to them; wherever, in brief, there are conditions which favour the excremental pollution of air breathed, of water drunk, or of soil on or near which dwellings stand,—there it is that the sanitary authority must be hard at work in applying remedies. When all this has been done effectively there may

Digitized by Google

be available sufficient information on which to apportion blame for the disaster of the past two months and for the continuance of the disease. It is as much the duty of a sanitary authority to see that its district is free from conditions that tend to harbour infection when imported or otherwise brought into its midst as it is for purveyors of either water or milk to see that their business is carried on so as not to endanger the public health. In most of these epidemics there is often blame on one side as well as on the other.

THE Council of the Hospital Sunday Fund is a cautious body. It spent nearly two hours on Wednesday in discussing a report on the out-patient department of the metropolitan hospitals, and ended by passing the following resolution:—

"That this Council recommend that at the next meeting of the constituents in December the following clause be added to the laws of the constitution: 'That where any hospital, having an out-patient department, has appointed a special and efficient officer for detecting any abuse in that department, it shall be regarded by the Distribution Committee as an important factor in determining the "merits."'"

Neither the report, which will be found in another column, nor the resolution based on it will excite the enthusiasm of those who realise the loose and pauperising way in which the out-patient department of some hospitals is conducted. If any relieving officer admitted applicants for parish relief in the way in which out-patients are admitted to the benefits of charitable medical aid he would soon be replaced by a more efficient successor. But familiarity breeds contempt, and it has accordingly come to pass that the governing bodies of our hospitals see this impracticable mass growing under their hands from day to day without realising its significance or with a sense of incapacity leading them to view with dislike all efforts to control it. They even come to approve it, to defend it, and to vaunt it as an argument of utility.

But though we are under no delusions as to the immediate effect of this resolution in reforming the out-patient department, it is, nevertheless, a step in advance, in that it has committed the Council of the Hospital Sunday Fund to the recognition of a chief measure for curtailing the out-patient department as a "merit" in a hospital. The quality of merit or demerit, according to the rules of the Hospital Sunday Fund, affects the award made by the Distribution Committee. It may be henceforth assumed, supposing the constituency to accept this clause, that a hospital without a special and an efficient officer for the detection of abuse in the out-patient department will be without one "merit," at least, on which the amount of its grant depends. The action of the Council on Wednesday shows its confidence—and very proper confidence too—that it does not exist merely to provide money for the hospitals, but to give friendly suggestions where these are necessary for their better administration, or for securing their benefits to those for whom they are meant.

The same discussion showed a great advance in the Council in the perception of the seriousness of the out-patient question and a disposition to put itself into harmony with public opinion outside. It would be simply disastrous if large funds were to be raised for hospitals from time to time without any guarantee being afforded that their distribution will be made on definite principles that will protect the poor and will at the same time prevent those that are not poor from pauperising themselves. A motion by Dr. GLOVER went, perhaps, a little further than Sir SYDNEY WATERLOW'S, and was apparently grateful to the Council, but in our opinion Dr. GLOVER showed a wise willingness to accept a motion from Sir SYDNEY WATERLOW, the Vice-President of the Fund and Chairman of the Distribution Committee, which was seconded by Sir WILLIAM BROADBENT who has been most helpful in this cause. No one could suspect him of having any designs against hospitals or the independence of managers of hospitals, but he has deep insight into abuses which demoralise the people and injure the profession. He has besides what is not universal in our profession, the courage of his opinions, and a power, amid abounding engagements, to give time to act as a leader, so that we are pleased to find ourselves for the second time in this issue of THE LANCET trumpeting his praises as an advocate of the rights of the profession.

The important matter of the distribution of the Fund has now for the first time become part and parcel of the out-patient question. There can be no doubt that much of the success which has attended the working of the Fund, apart from the efforts of the gentlemen who compose its Council and Committees, is due to the confidence which the public have always placed in the Distribution Committee. With a view to increasing this confidence some of the members of the Fund, and notably Sir HENRY BURDETT, have from time to time asked the Chairman of the Distribution Committee to disclose the mode of distribution of the Fund. This Sir SYDNEY WATERLOW has now done in the Board-room at Charing-cross Hospital on Thursday last, and his words cannot but increase the public trust in the administration of this great charity. We shall publish Sir SYDNEY WATERLOW'S statement next week.

Annotations.

"Ne quid nimis."

PROFESSOR MACEWEN AND THE MANAGERS OF THE GLASGOW WESTERN INFIRMARY.

THE difficulties of the managers of the Glasgow Western Infirmary in connexion with new arrangements of their wards and beds are still causing much anxiety both to them and to those who have the best interests of the University of Glasgow and of medical education at heart. The managers of the Western Infirmary met on Tuesday to consider the questions in dispute between them and Professor Macewen. They were nearly all present, and all but one (Professor Moir) agreed to the publication of a statement by them defining their duties on the one hand to the public to make adequate provision for the care of the sick, and on the other "to make," in consideration of a money payment from the University to the infirmary, "such reasonable provision as is deemed necessary by the Senate of the University of Glasgow and

Digitized by Google

the managers for professors of the University engaged in clinical instruction.' The managers traverse with considerable force many of the statements which have been made on this subject, while they express their pride at the connexion of Professor Macewen with their institution. They are evidently in the great difficulty of having to meet the demand for more beds than they can well supply. We think that if this aspect of the case is taken into consideration and a little time given on both sides a solution of this question should be reached. The colleagues of Professor Macewen presented to the managers a very strong and dignified statement regretting the resolution to take away from their distinguished colleague twelve of the beds which he uses so well, and especially that it should have been done without "some inquiry" beforehand into "the disadvantages to which his surgical work and teaching will be subjected by the change proposed." It seems obvious from the very terms of the deed of agreement with the University that the Senate of the University should have been consulted before changes so deeply concerning the interests of medical education in the University were resolved upon. On the face of this representation from the Senate it appears that in restricting the beds at Professor Macewen's service the managers are failing "to make the provision deemed necessary by the Senate." We in no way forget the claims of other professors or the difficulties of the managers, but we look confidently for a solution of the difficulties in a sense that will satisfy Professor Macewen and his colleagues in the Senate. There are times when a school or a university is represented by one of its number. This is such a time. It is not a mere question of surgery which Professor Macewen so brilliantly represents. It is a question of therapeutics, towering over all other questions in therapeutics, in its range, and its importance, and we think that his claims, viewed in this light by the managers, will lead them to conclude that some way must be found to leave him in undisputed possession of his present facilities for teaching.

THE REPORTS OF THE ROYAL COMMISSION ON VACCINATION.

IT may save confusion, or add to it, if we endeavour to explain how matters stand with regard to the publication of the reports, with appendices, of the Vaccination Commission. In all seven reports have been issued. Strictly speaking, each of the first four reports consisted merely of a preliminary note to a volume of minutes of evidence and of appendices to minutes of evidence. These four volumes of minutes of evidence, containing also their relative appendices, are, however, conveniently called the first four reports of the Commission. Each of these four volumes was provided with a good analytical index. Volume I. was published in 1889, Volumes II. and III. in 1890, Volume IV. in 1893, and Volume V. in 1892. The fifth report, which it will be noticed was published before the fourth, was a short document in which the Commission stated their disapproval of repeated prosecutions for neglect of vaccination. Next in order should have come the sixth report; this report, however, was not issued until the present year. Like the first four, the "report" itself is a mere preliminary note, the volume being made up of minutes of evidence and appendices to these minutes of evidence. It differs from the first four volumes in being very much bulkier than any of them and in being published without an index, so that, though it contains the evidence of about eighty witnesses, it is rendered practically useless for purposes of reference. In the interval between the publication of the fifth and sixth reports the final, or seventh, report was issued in 1896, and also without an index. The volume containing this report contains also the Statement of Dissent by Dr. W. J. Collins and Mr. J. A. Picton. Page 6 of the volume gives a "List of Appendices to the Commission's Final Report." But the volume itself contains only the first two appendices mentioned in the list. Appendices III., VII., VIII., and IX. have not yet been published. Appendices VI., V., and IV., however, have now been issued within a few days of each other, Appendix VI. appearing before Appendices V. and IV. Each of these appendices is itself a report, Appendix VI. being Dr. Sidney Coupland's report on the Outbreak of Small-pox in Leicester in 1892-93, Appendix V. Dr. T. D. Savill's report on Small-pox in Warrington in 1892-93, and Appendix IV. Dr. Luff's report on Small-pox in London in 1892-93. These three appendices are published without an index. The appendices yet unissued are to consist of reports on Small-pox in Dewsbury, Gloucester, &c., and of papers relating to cases of injury alleged to be connected with vaccination. It is not known when they will be published or whether they will be indexed.

THE PUGILIST AND THE HOSPITAL.

BOXING has always been one of our national sports, and the National Sporting Club is, we believe, the Mecca of the champions of modern pugilism. We at all events have nothing at the moment to say against it, and are only gratified to learn that a British youth known as "Pedlar" Palmer has recently there met and defeated another "bantam" of Irish-American extraction and been rewarded with a purse of £600. It is also interesting to learn from a contemporary that Mr. Palmer, who is not yet twenty-one years of age has won over £3000 in stakes alone during the past two years, while we congratulate him on the pluck which enabled him to go on and win his last victory fighting nine rounds after one or both of his hands had given way. The same authority informs us in a succeeding issue that the injury consisted in a fracture of the small bone of the left arm, and adds a statement which seems to us almost libellous as it stands. It states that the injury was not discovered till "he went to the Poplar Hospital on the next day to have the hand dressed." We feel sure that "Pedlar" Palmer would as soon winter in the workhouse as accept surgical aid at the expense of a charitable institution, and that if our contemporary's account is correct so far as it goes it has omitted to mention that a cheque for at least £50 out of the last £600 has found its way into the coffers of the Poplar Hospital from the pocket of the grateful pugilist.

THE HEALTH OF THE NAVY.

THE question of how to instruct our naval medical officers in the pathology, prevention, and treatment of tropical diseases is now being debated in the columns of the leading daily journal. It has been suggested that the medical officers at Haslar Hospital should give courses of lectures to the junior naval medical officers as they enter the services. But, as Dr. Walter Reid, Inspector-General, R.N., points out in his letter to the *Times* of the 26th inst., "the great difficulty in the way of success with such a plan is to find a medical man in the service, or, for the matter of that, elsewhere, with the requisite qualifications, particularly as to a knowledge of tropical diseases and of the various modifications in health liable to occur during the service of men abroad. He would require to be a man who has spent years on each of our foreign stations. It would be necessary that he should have had opportunities of seeing and working through several great tropical epidemics, when or wherever they should happen to occur. He would require, for instance, to have been at Hong-Kong the other day for plague, elsewhere for a cholera epidemic, and in the West Indies during one of yellow fever. He would require to have

Digitized by Google

wide experience of malarious disease in the many forms which it assumes in different parts of the world. It is safe to say, and no disparagement to naval medical officers, that such a man cannot be found. It would be almost impossible to make him, for he would either be dead or past his work before he had time to acquire the necessary qualifications. The truth is that under ordinary conditions of service the medical officers do not see much of the graver forms of tropical disease except when employed on shore, for the rule is, as it ought to be, that our ships avoid unhealthy ports, or when they must visit them then they leave them as soon as possible. The great watchword which must guide all their endeavours is prevention." The Dean of the Medical School of St. George's Hospital writes on Oct. 23rd that lectures in tropical medicine are delivered there by Dr. Patrick Manson. This is certainly a step in the right direction; but we must remember that Dr. Manson, being physician to the Seamen's Branch Hospital, Albert Docks, and not to the Seamen's Hospital, Greenwich, or old *Dreadnought*, has only some eighteen beds at his disposal, and that these do not afford much clinical material to work upon. Dr. Reid makes a suggestion which we think a good one. It is that the old plan of issuing an annual report on the health of the navy, which used to be carried out under the superintendence of Dr. Mackay, should again be followed. This used to be compiled from the various medical officers' journals and reports, and was, Dr. Reid says, of great value. These reports are still sent to headquarters, but the only report which appears is "practically nothing more than a bald collection of statistics." We should say the sooner "my lords" return to the old style of report the better. All Government departments have a mania for saving halfpence and spending pounds, but the little extra money which a reversion to the old system would cost would be more than counterbalanced by the value of the information which would be put into the hands of those responsible for the health of our first line of defence.

MR. STEAD AND THE CONTAGIOUS DISEASES ACTS.

THE editor of the *Review of Reviews* has degenerated into language concerning the Contagious Diseases Acts that is more than abusive; it is actually rancorous. In an article headed "Our Real Peril in India," which appears in the current number of the journal in question (p. 368), after expressly saying that he does not "wish to assume that the allegations so freely made on the one side and tacitly admitted on the other are really correct," and after announcing his belief "that current reports may be exaggerated, and the Indian authorities may not be doing all that they are credited with," this perfervid champion of free trade in venereal disease commits himself to the following extraordinary statement: "Certainly if the Indian army is to be run by such unscrupulous rogues as those army doctors who are responsible for the cooked statistics with which they have defiled the name of the country and such mutinous officials as those who have set Lord George Hamilton's directions at naught there would be good reason for setting on foot an agitation against enlistment, which would only need a little encouragement to paralyse the War Office." There can be but one opinion regarding a controversialist who thus stultifies himself within the space of a few lines while offending against decency by his outrageous diction. That opinion is that his case is a woefully poor one. As an example of idle vituperation the passage we have quoted might be thought hard to beat; but a little further on in the article there is another outburst which perhaps beats it. Here it is: "Of course, I shall be told at once that I am indifferent to the sufferings of the soldiers, and that if we have not this system we shall see the army eaten up with disease. To which assurance I have simply to make one straight answer—namely, that those who make it lie in their throats and if they had an elementary knowledge of the facts they would know that they lied." Precisely so! Now those unscrupulous rogues, the army doctors, happening to possess elementary, to say nothing of exhaustive, knowledge of the facts are perfectly well aware who is "lying in his throat" or in his journal, as the case may be. Intemperate language is generally the sign of a bad case, and it would be difficult to find a more effectual proof of the unsoundness of Mr. Stead's views than his own utterances, so we continue to quote from him. Here, for instance, is a passage which clearly convicts its writer of prejudice, not to say fanaticism: "The service is not too popular to-day, but if we are to be taught that it is only an ante-chamber to the brothel and the lock hospital the difficulty of recruiting will speedily be increased to a degree which would give Lord Wolseley the nightmare. If we have a few more dissertations like Colonel Turner's, Lord Lister's, and other men of that kind, it may very soon become a duty to convince the masses of the people that the army in India is no fit place for any decent woman's son." What drivel! Now, just one last example of the depth of Mr. Stead's knowledge, without a belief in the possession of which, we suppose, he would hardly have written in this way about "rogues" and "lying in throats." He accuses Colonel Turner of "effrontery" in asserting that "on the Continent youth is generally and efficiently protected by State legislation," and then, in order to demolish his military adversary, he quotes from a "dignified and effective rejoinder" by the Rev. J. Kirk Maconachie, who says: "The French hospital returns show that between 60 and 70 per cent. of venereal disease is contracted from 'protected' women." Clearly Mr. Stead imagines, or would have us believe so, that these "protected" women are registered and periodically examined prostitutes. Does he not know the phrase "protected" women as used for "kept" women, and that such "protected" women are under no police control at all? If he is ignorant of these things he is not in a position to discuss the Contagious Diseases Acts. If he knows them he would appear to have been—well, equivocating in his larynx.

YELLOW FEVER.

IN the *New Orleans Medical and Surgical Journal* for October are four articles on Yellow Fever. The first, on Etiology and Pathology, is by Dr. R. Matas; the next, on Symptomatology and Diagnosis, by Dr. F. W. Parham; the third, on Treatment, by Dr. T. S. Dabney; whilst Dr. J. J. Archinard reports a case with the necropsy. The paper by Dr. Matas gives an interesting historical account of the researches which have been carried out concerning the nature of the fever and the efforts which have been made to discover its cause and the mode of diffusion of its contagion. A full description is given of the micro-organism isolated by Dr. Sanarelli this year, and reference is also made to the organism discovered likewise in the present year by Dr. Havelberg. He concludes his paper by considering what bearing Sanarelli's discovery, if verified, has upon the prophylaxis, diagnosis, and treatment of yellow fever, and sums up as follows: 1. As to prophylaxis. It is legitimate to expect that in dealing with so specific and potent a micro-organism as the bacillus icteroides it is possible, by attenuated culture or by an antitoxic serum such as is now obtained from immunised horses after subjecting them to experimental diphtheria or tetanus, that a reliable preventive and curative agent will be obtained. 2. As to diagnosis. That if the cultures obtained from the bacillus icteroides are specifically characteristic, as claimed by Sanarelli, a pathognomonic

Digitized by Google

culture may be obtained in twenty-four hours from suspected cases. Again, if this should be impracticable during life, owing to the paucity of germs in the blood, it is possible that a specific serum reaction similar to Widal's agglutination test may be obtained, which will permit of an immediate and infallible diagnosis in the early stages of the disease. 3. As to treatment. The greatest value of Sanarelli's researches lies in the prospect of obtaining a specific antitoxin which alone can cope with the specific cause in the blood and the tissues. Apart from this, these researches would suggest some important conclusions which affect our present mode of treatment—for instance, that resorting to germicidal medication with the view of destroying the specific micro-organisms in the gastro-intestinal tract is of no use. When the symptoms of yellow fever present themselves the specific germ and its toxins are already in the blood and tissues, and no amount of purgation or gastro-intestinal antisepsis could possibly affect its future course or development. On the other hand, in view of the secondary affections which so frequently complicate this disease by the invasion of the colon bacillus and other bacteria of the gastro-intestinal tract in the graver types of this infection, it is perfectly logical and proper to resort to laxatives and intestinal antiseptics and a total abstinence from all foods, with the view of diminishing these secondary intoxications to a minimum. One of the fundamental and pernicious errors in this disease, according to Dr. Matas, is the belief that food is necessary in its treatment because it is a prostrating disease. This is not a wasting disease, and when it is typical it is self-limited and of comparatively short duration. The cry of the organism is not for food, which will only help to clog up the machinery of elimination, but for water, which is needed to dilute the toxins in the blood, to maintain the secretions of the poisoned organs, the skin, and, above all, to flush out the kidneys, which are blocked up so early in the struggle.

THE UNQUALIFIED PRACTITIONER AGAIN.

AN inquest was recently held in Singapore upon the body of a man who died after taking an overdose of chloral. It should also be added that he was suffering from delirium tremens and was a chronic alcoholic. The interest of the case, however, lies in the fact that the deceased was treated by an unqualified person named Max Wispauer, who in his evidence described himself as a German and a chemist, and said he was not allowed to practise in his own country. He examined the deceased's heart very carefully and gave him what we must allow were sound instructions. He also prescribed bromide and chloral, which drugs are well known to be useful in the case of delirium tremens. But, as everyone knows, persons in this condition require very careful watching during the exhibition of these drugs, and this Mr. Wispauer omitted. This we may see from the verdict, which ran as follows:—

"Death was due to an overdose of chloral hydrate acting on a weak heart. So large a dose as 30 grains of chloral hydrate following 24 grains of chloral hydrate taken during the day, and followed by a similar dose of 30 grains of chloral hydrate, should not have been given in the weak condition of deceased's heart. The chloral hydrate was prescribed by Mr. Wispauer, and he ought to have visited the deceased to note the effect of the first dose of 30 grains of chloral hydrate before allowing the second similar dose to be given. The chloral hydrate was dispensed by Mr. Wispauer, and he was negligent in not writing full directions on the label of the bottle, particularly as he considered the deceased to be suffering from a disease affecting the mind. For if so it was natural to expect that verbal directions might be forgotten or not implicitly followed. Thus in prescribing and in dispensing a poisonous drug so uncertain in its action as chloral hydrate Mr. Wispauer was negligent.

"*Rider*—It is to be regretted that no ordinance exists in this colony to prevent unqualified persons from treating dangerous diseases and prescribing poisons. This colony appears to be the only one where such an unfortunate condition exists."

The colonies are in this case much better off than the mother country. Over here any swindler, however ignorant, can practise as much as he likes and no one can say him nay, so the quack, the faddist, and the cheat may sing in chorus, "Oh! what a happy land is England" Perhaps the advent of Mr. Horsley on the General Medical Council may bring about a better state of things.

SUDDEN DEATH OF A PRISONER.

SOME interesting medical evidence was given the other day at an inquest held in Lancaster Castle on the body of a prisoner who had been found dead in his cell. It appears that he had been an inmate since last June and had often complained of pain in the head and had suffered occasionally from vomiting. In consequence of this he was frequently seen by the prison surgeon. At the post-mortem examination an erosion of the base of the skull of about the size of a shilling was found. Lying upon this was a "softened mass" containing spicules of bone. This seems to be one of those perplexing cases in which gross lesions give rise to few signs or symptoms during life. The vomiting does not seem to have been at all severe, and, of course, as regards the pain, we have only the patient's word. It is not stated whether any ophthalmoscopic examination was made. This, if it revealed optic neuritis, would complete the list of classical symptoms of cerebral tumour. There was a history of a severe fall some months before, and it seems possible that the softening was caused by localised periostitis due to this, or more probably to syphilis.

THE CASE OF DR. LAPORTE.

WE publish in another column a report of a case in which Dr. Laporte, of Paris, was sentenced to three months' imprisonment for alleged negligence in attending a woman when craniotomy had to be performed. It is true that under a law similar to that sometimes exemplified in this country in the case of first offenders the actual infliction of the penalty has been postponed for five years on condition of good behaviour in the meantime, and that if no cause of complaint arises during that period the penalty will not be inflicted. Still, the stigma of the sentence remains, and for that reason much indignation has been excited at the result of the trial. The evidence against Dr. Laporte appears to have been to a great extent of an unsatisfactory kind. It seems to have consisted of the impressions formed by the husband and two neighbours by watching what was done from outside the room through an aperture left by the door of the room not being quite closed. They formed the opinion that Dr. Laporte had applied the forceps in an improper manner. It is difficult to imagine anything more unsatisfactory. How could people unfamiliar with obstetric science possibly come to any useful conclusion on the subject, even if they had been in the room? To the eye of the layman the amount of force often used in difficult forceps cases might easily appear excessive, violent, and therefore improper. As Professor Pinard testified, the fact that the forceps was applied four times, and that nevertheless no lacerations of the vagina and neighbouring organs were found after death, sufficiently disposes of the suggestion that the instrument had been improperly applied. A less satisfactory part of the case is that when craniotomy was decided upon Dr. Laporte appears to have been without the proper instruments, and to have used a long needle instead of the perforator. The woman died two days after the operation, and at the post-mortem examination two perforations were found in the bladder which were supposed to have been caused by the needle. Even supposing these perforations to have

Digitized by Google

been caused by the needle, unless the peritoneal coat of the bladder was perforated it is not easy to see how anything worse than incontinence of urine should have resulted. The patient had always had difficult labours, and yet her husband seems to have left her all day long without skilled assistance and only to have sent for a medical man in the evening. It seems only too probable that the unfortunate termination of the case was due to leaving the woman to become exhausted before sending for help. At the same time the case appears to us to teach a useful lesson. If the medical man has not the proper instruments he is extremely likely to be held responsible for whatever happens. We think it would have been more judicious if, when he found craniotomy necessary and knew that he was without the instruments usually employed, he had sent to a lying-in hospital for help. In a large city such as Paris it is surely always possible to overcome a difficulty of the kind in this way.

PROSECUTION UNDER THE DENTISTS ACT.

A PROSECUTION under the Dentists Act has recently taken place at Lichfield, as is reported by our Birmingham correspondent. The plaintiff, a Mr. Morgan, was found guilty and fined £2 2*s.* with costs for using the term "dentist" and not being duly registered. The interesting feature, however, of the case was the endeavour made to obtain a conviction for "obtaining money under false pretences." The plaintiff's daughter had two teeth fitted, for which she paid the sum of 7*s.*, and at the time of the operation the defendant, on being questioned, stated he was Mr. Morgan, "the dentist." The prosecution proved that he was not a duly registered dentist and therefore not entitled to practise, and contended that he had by using the term "dentist" led the patient to believe that he was so registered, and had therefore obtained the money—namely, 7*s.*—under false pretences. The court dismissed the case, the defendant's counsel pointing out that in order to establish such a charge, not only was it necessary to prove that the statement relied upon was untrue, but also that it had influenced the person to pay the money and was made with the intention to defraud. The case is of some interest, not only to the dental and the medical professions, but also to the general public, and although we have no wish to question the decision arrived at in this case, we cannot help feeling that in the majority of instances the assumption of a false title by such irregular practitioners is done with the object of obtaining money under false pretences.

THE PROGRESS OF PUBLIC HEALTH SINCE 1837.

MEDICINE, in common with other branches of natural science, has undergone great development in every department during the sixty years of Queen Victoria's reign. Much light has been cast on the difficult problems presented by morbid phenomena, and there has, moreover, been a marvellous extension of the utilitarian applications of medical science, especially in the prevention of epidemic disease and in the improvement of operative surgery, which has been almost revolutionised by the discovery of anæsthetics and antiseptics, the net result being a great saving of life and diminution of suffering. To write the history of the evolution of sanitation as at present existing would be a task of no small magnitude, but many expositions of selected parts of the subject have from time to time appeared, one of the most recent being a presidential address delivered in the Council House, Birmingham, by Dr. T. R. Bailey, medical officer of health of Bilston, at a meeting of the Midland Branch of the Society of Medical Officers of Health. Cholera, typhus fever, and typhoid fever were the examples which Dr. Bailey employed to illustrate the efficacy of sanitation in reducing the incidence of disease, small-pox coming rather under the head of vaccination. On the subject of typhus fever he said: "In 1837 the disease prevailed in many parts of England, and in 1838 no less than 1271 per million of the population died from it. In the years 1846–48 a frightful epidemic occurred in Ireland on the failure of the potato crop. It spread to England, where, in 1848 786 cases were admitted into the London Fever Hospital alone. In that hospital as many as 14,589 cases were treated during the period 1832–70. In Glasgow, too, the death-rate per million for the five years 1855–59 was 1265, and for the five years 1860–64 1576. These figures show the extremely fatal character of this most formidable disease. Since 1869 this fatality has markedly and continuously decreased until now it has almost reached the vanishing point. In that year the deaths in England and Wales were 4281, in 1895 they were only 318, and the mean rate for the quinquennium 1891–95 had actually been reduced to 4 per million of persons living. ..... Surely if sanitarians could lay claim to no other achievement they would be entitled by this to an honourable place in the history of the Victorian era."

THE PREVALENCE OF TYPHOID FEVER.

UPWARDS of two hundred cases of typhoid fever have been notified in the town of King's Lynn, and the Local Government Board have asked the sanitary authority for an explanation. Contradictory statements are prevalent as to the probable cause of the outbreak, allegations being made against the main sources of the water-supply as well as against the filtering arrangements. The sanitary authority attribute the mischief to pollution of the supply by surface water after a thunderstorm. We are informed that there is also a scattered outbreak of typhoid fever in different parts of Essex which is attributed to the consumption of uncooked oysters from one of the beds at Brightlingsea which was shown in the official report on "Oyster Culture in Relation to Disease" to be subject to risk of sewage contamination. Dr. George Buchanan, who has been instructed by the Local Government Board to inquire into the occurrence, is already on the spot.

THE TREATMENT OF INCONTINENCE OF URINE IN CHILDREN.

A USEFUL paper on this subject, by Dr. J. A Coutts, is published in *Treatment* of Sept. 9th, 1897. He states that the vast majority of cases of nocturnal incontinence can be relieved by waking the child at stated intervals to micturate. Restriction of liquids during the latter hours of the day will help. But in a few cases this seemed to keep up the disorder, the vesical mucous membrane being evidently intolerant of the highly concentrated urine so produced. In obstinate cases if the urine is of high specific gravity and acidity then the child should be encouraged to drink freely towards the end of the day. A signal success may be thus achieved. Of drugs belladonna still is foremost, but it often fails. This sometimes arises from the common method of giving several doses during the day. A much more efficient one is to give one single large dose in the evening, which can be gradually increased every four or five days, and when the incontinence ceases gradually diminished. If belladonna fails recourse must be had to other drugs. Of these he places most reliance on lycopodium, the merits of which have been as yet but little recognised. He gives twenty drops of the tincture three times a day to a small child, and increases the dose gradually to a drachm. Possibly more could be given. He knows of no poisonous properties attaching to the drug, but admits he may be at fault in that respect. In ordinary cases bromide of potassium has proved of less service to him than to some

Digitized by Google

others. But there are cases in which it may prove of the utmost benefit—those in which micturition occurs when waking is imminent or takes place. He has seen but little benefit from strychnine, but in combination with iron in cases accompanied with anæmia and lassitude it has been of great service. When drugs fail there remain other methods. In many instances micturition does not occur while the child lies on his side, but immediately when he turns on his back. Here a bobbin strapped over the lower spine is effectual. Circumcision is to be recommended only where there is undue tightness of the prepuce.

A NEW METHOD OF INDUCING SLEEP.

IN the *Journal of the American Medical Association* of Sept. 25th, 1897, Dr. J. B. Learned describes the following method, which he used in his own case. For some years he suffered from insomnia following a fall from his car. He tried many methods of treatment in vain—drugs, hot water and cold water internally and externally, friction, over-feeding and under-feeding, exercise, gymnastics, deep inspirations, and numberless mental occupations. At last the following method proved a success. The principle is to induce muscular fatigue by exercises carried out in bed. Lying on his back the patient first reaches for the foot and head board at the same time. He then raises his head half an inch; at the same time he breathes slowly and deeply about eight inspirations to the minute, which are counted. After about twenty inspirations, the head, which begins to feel heavy, is dropped. The right foot is then raised (the reaching for the boards and counting being continued) and similarly dropped when fatigued. The left foot goes through the same process. The muscles which are used in reaching for the head and foot boards are then relieved, and the body is elevated so that it rests on the head and heels. He then turns on the right side and reaches for the head and foot boards again, and raises first the head and then the foot as before. The same process is gone through on the other side. Thus eight positions have been assumed and a large number of muscles used. If sleep has not been induced the same cycle is gone over again.

PROPOSED AMENDMENTS IN THE NOTIFICATION ACTS.

WE have received from Dr. Meredith Young a special report on the working of the Infectious Diseases Notification Act which he has addressed to the Crewe Town Council. Whilst we agree with him that in certain respects the present Act needs alteration, we doubt if it should be modified in a number of the respects to which this report refers. Dr. Young would leave the fee at 2*s.* 6*d.* for a first certificate of notification, but proposes that if a second case of infectious disease arises in the same house "within one month from the date of such certificate," only 1*s.* should be paid for the second notification, and that the reduced fee should apply to all cases of scheduled disease, and not merely to cases of the disease primarily notified. For example, a case of scarlet fever notified by one practitioner on Oct. 1st is to be paid for at the rate of 2*s.* 6*d.*, and a case of small-pox occurring in the same house on Oct. 31st, although it may come under another medical practitioner's care, is to be paid for at the rate of 1*s.* The idea is that since one notification has brought the infected premises under notice the value of the second notification is decreased. If this means that, assuming the case of scarlet fever to have been removed to hospital on Oct. 2nd, the medical officer of health is to have the place kept under supervision until the expiration of a month, then we fear that the sanitary officers in large populated districts will have their hands very full; if it does not mean this, the notification of Oct. 31st will be of just the same value for public health purposes as that of Oct. 1st. Then, again, Dr. Young proposes that in the case of chicken-pox and small-pox, diseases that are often mistaken for each other, the former should be notified for 1*s.* and the latter for 2*s.* 6*d.* He could hardly have selected two diseases which give more trouble as regards diagnosis, especially in a vaccinated community; indeed, there is no less trouble involved in the ultimate diagnosis when the disease is decided to be chicken-pox than there would be if it were a case of small-pox. Other points that are equally difficult to be understood occur in this report, but we have not space to discuss them. We hope, however, that before any further action is taken in the matter the views of those who will be mainly affected by such changes will be ascertained, and that lessened fees will not be proposed precisely in those cases where the greatest difficulties to notifying practitioners arise. The subject evidently requires more attention than it has yet received in Crewe, but we are informed that the corporation have, since receiving this report, already memorialised the Local Government Board in the matter.

CRUELTY IN A WORKHOUSE.

THE case of an imbecile, aged sixty-three years, whose death occurred in the Bradford Workhouse, was recently investigated at a coroner's inquest. The deceased had been a week in the workhouse, when he was placed, being then in a feeble and restless condition, under the care of one of the attendants. This man, who it is admitted was somewhat the worse for drink, was observed by a ward assistant to strike the deceased, and, according to the testimony of an imbecile inmate, he otherwise violently assaulted him. The death of the latter occurred a day later, and a post-mortem examination showed that several ribs were fractured and that cerebral hæmorrhage had occurred. There was, however, no evidence connecting this hæmorrhage with external injury. The fine point between *post* and *propter* in this instance cannot perhaps be decided with judicial precision. We are consequently unable to define the exact relation between the death and the ill-usage which preceded it. Nevertheless, it is quite clear that the dead man had been treated with unjustifiable violence, and we have no explanation but this to account for his visible injuries. It is therefore surprising to find his attendant dismissed by the coroner and his jury with no further comment than a reprimand for his cruelty. The case, we should have thought, was at least one of aggravated assault and therefore punishable. It is at least to be hoped that the Bradford Workhouse authorities do not think so lightly of their servant's misconduct as to retain him in a position for which he is so evidently unfit. This case, moreover, points another lesson — namely, the duty of observing a more careful supervision over ward attendants as well as greater care in their selection.

THE PLAGUE IN INDIA.

WE have so frequently called attention to the increased occurrence of plague, and to the large increase of sickness and mortality in the towns and districts which had previously suffered from the epidemic, that there is no need to enter upon the subject at any length at the present time. Unfortunately, if we may judge from past experience of the disease in China and elsewhere, an increased prevalence of plague may be expected to occur during the ensuing winter season, and the slow and insidious way in which it is extending itself in India is also a very serious matter. Several Europeans have been attacked during the progress of the epidemic, and we now learn, through Reuter's agency, that it is officially announced that the disease which has appeared in the Jullundur district of the Punjab is true

Digitized by Google

bubonic plague. A cordon has been drawn round the infected area. Plague has also appeared in Hubbi and Wai, on the road to Mahabalishwar. At Poona 294 cases are reported from the hospitals and 115 at Bombay. A revived activity of the disease at the beginning of the cold weather was predicted; but the recrudescences in cities that have already suffered are generally of a much milder character than the primary outbreaks. It is the slow dissemination of the disease in rural districts and the difficulty of promptly dealing with it before the infection has gained any foothold in these places that renders the task so onerous and perplexing. Isolation and hospital treatment of those stricken with the disease and the application of effective sanitary measures, including the removal of filth and the opening out of infected localities freely to the air and sunshine, are the obvious remedies; but how to apply these promptly is surrounded with practical difficulties, for it takes time and money, a large staff of officials, a strong administration, and a numerous executive to do it, to say nothing of the provision of numerous isolation hospitals and camps. The Government of India will save themselves an enormous outlay of money and trouble, it appears to us, by devising, through the instrumentality of their medical and other officials, some organised system of dealing with the spread of the disease which is capable of being worked without leading to such an obstinate opposition and resistance on the part of the natives as to render their efforts futile.

PHOTOGRAPHY AT THE NEW GALLERY.

THE kodak, or some similar form of camera, has now become almost a necessity for the traveller and the holiday maker, for it is so portable and easy of manipulation that the many thousands who cannot sketch and yet are desirous of preserving some record of what they see, can by means of a portable camera fitted with films possess as many illustrations of their journeys as they please. Nor are the benefits of photography confined to these uses, for a knowledge of the art is specially useful in medicine and surgery. The Eastman Company, who were we fancy the pioneers in this country of film photography, have opened a very interesting exhibition of apparatus, methods, and results at the New Gallery. The various gradations of toning and colouring which are obtained by the use of different chemicals are quite a revelation, though we cannot agree with the endeavour which is obvious to make a photograph look as much as possible like a water-colour drawing. Compare even the most finished sepia print of a landscape or seascape with the prints of the Liber Studiorum or a sepia sketch of a master like the late Alfred Hunt, and what a difference there is: in the one there is the very soul of th eartist, in the other nothing. A photograph should be a photograph and not attempt to be anything else. Among the radiographs exhibited is a very perfect series of twelve prints of the same hand obtained at one sitting by super-imposing twelve plates one above the other. These were taken on the Eastman x ray paper with a three minute exposure. A variety of cinematograph films were also on show, and the Eastman Company have great hopes that as the apparatus is more perfected it will be possible to obtain radiograph cinematograph films of the joints of the human body, a procedure which would add largely to our knowledge of their structure and functions. Dr. Macintyre, of Glasgow, has for some time been working at this subject and has arrived at some very good results in the frog; but at present the difficulties with regard to human joints—e.g., the knee—have not been overcome. We have mentioned that portion of the exhibition which appeals most to medical men; but in the west gallery there are many very beautiful landscapes and other prints which are well worth seeing, notably Nos. 3 and 5, by Mr. A. Pringle, and No. 11, by Mr. A. Sutcliffe, though it must be remembered that even these are not water-colours.

CITRATE OF IRON AND STRYCHNIA MISTAKEN FOR CITRATE OF IRON AND QUININE.

A RECENT inquest which was held at Gainsborough illustrates the great care which is necessary in selling and dispensing drugs which are poisons and which resemble in appearance drugs which are more or less harmless. It would appear that a woman purchased from a druggist what was sold to her as two-pennyworth of citrate of iron and quinine, but which was in reality citrate of iron and strychnia. The error arose from the fact that the wholesale druggist who supplied the local druggist forwarded in response to an order a bottle labeled in accordance with the order, but containing the poisonous drug. From the evidence given by a representative of the wholesale firm in question it was elicited that citrate of iron and quinine is sent from the factory to the warehouse in tins, whilst citrate of iron and strychnia is received in earthenware jars. The two different combinations of drugs are kept in different rooms, but may be brought into the bottling-room for the purpose of being packed and labeled. The assistant of the local druggist who sold the drug stated that he weighed exactly two scruples, and that two-thirds of the bottle from which he dispensed it had already been sold. As the result of the inquiry the jury returned a verdict to the effect that the woman died from poisoning by strychnia, sent by mistake for citrate of iron and quinine to a local druggist by the wholesale firm of manufacturers in London with whom he usually dealt. They added a rider recommending that the wholesale firm should in future adopt a system in regard to their business of checking those who fill and label bottles, as adopted by many large firms in other trades. They also cautioned the assistant as to weighing in future the ingredients for medicines.

CHRIST'S HOSPITAL SCHOOLS AT HORSHAM.

THE ceremony which took place at Horsham on Saturday marks, it is to be hoped, the end of the unfortunate state of things which has perturbed the minds of the governors of Christ's Hospital and of the general public for some years past. It will be remembered that about seven years ago it was decided to remove the school from Newgate-street in accordance with the scheme of the Charity Commissioners under which the governors were empowered to dispose of the city site and buildings. The financial condition of the charity, as well as general considerations of health and sanitation, rendered this necessary, and a site was selected at Stammerham, near Horsham. Objections, however, from a sanitary point of view were made to this site, but the governors having already purchased it did not feel inclined to seek for a new one. By judicious sanitary measures it was pointed out that the existing drawbacks to the situation might be removed. These difficulties have now, we trust, been overcome, and the first step towards the erection of the new buildings was made on behalf of the Queen by the Prince of Wales on Oct. 23rd, when he laid the foundation stone with the same trowel that was used by his great uncle Frederick, Duke of York, on behalf of George IV., in 1825, the year in which that Prince laid the first stone of the great hall of the historic building in Newgate-street. The new site covers nearly 1200 acres and is situated on rising ground. The residential portion will have a southern frontage with ample interspaces between the house blocks, while the working portion will be placed in the centre and disposed at intervals about a cloistered quadrangle. At present it is intended to erect six house blocks, divided into two houses, each

Digitized by Google

for fifty boys and two masters, with domestics and staff. The blocks will be connected by a subway, ventilated and lighted throughout, and containing the pipes, mains, and electrical wires so as to afford facility of examination and repair. The buildings include an infirmary, sanatorium, library, and museum. The accommodation will be for 600 boys, instead of for 620 as originally intended, but it is hoped that eventually the buildings will be completed in accordance with the original designs. The London, Brighton, and South Coast Railway Company has undertaken to build a station on the estate, to fix cheap fares, and to provide other facilities for reaching the station.

THE DEATH OF THE DUCHESS OF TECK.

IN the Duchess of Teck, whose lamented death occurred last Wednesday morning, the nation has lost not only a most popular member of our Royal Family, but also a lady whose warm heart, untiring kindness, and practical sympathy with distress had been placed in evidence in a thousand ways. Her intimate association with numerous philanthropic projects for the good of the suffering and the weak, especially those which had for their object the relief of women and children in distress, had endeared her to the heart of the nation to a remarkable extent, so that her appearance on public occasions was always the signal for a reception the enthusiasm of which left no doubt as to the real affection in which she was held by all. It will be remembered that in April last Her Royal Highness underwent an operation for strangulated umbilical hernia at the hands of Mr. H. W. Allingham. The operation was completely successful, and every one was glad to see the Duchess's stout handsome face at the Jubilee festivities, when she was apparently enjoying her usual health. Latterly, however, she had been troubled both by a feeble heart and glycosuria—both pathological conditions being of some years' standing—and on more than one occasion when indefatigably fulfilling her part in some public function she has appeared to those around her to have been undertaking more than her strength warranted. The Duchess was taken ill on Monday morning last, when she was seen by Dr. Wadd, of Richmond. On Tuesday she manifested slight symptoms of obstruction, and in the course of the day was seen by Mr. Allingham in consultation with Dr. Wadd. In the evening the symptoms became suddenly severe, and Mr. Allingham was again summoned. It was then decided by Mr. Allingham, Dr. Wadd, and Mr. H. Randall Wadd that the only prospect of relief lay in an immediate operation to release a strangulation of the bowel. This was performed by Mr. Allingham, Dr. Hewitt administering the anæsthetic, and a strangulation was found in the neighbourhood of the old umbilical sac. The operation was immediately successful in that all the symptoms were relieved, and she came round from the anæsthetic, but two hours later she died from cardiac failure.

HYDROPHOBIA?

A DEATH attributed to hydrophobia from the bite of a dog formed the subject of an inquest held at St Bartholomew's Hospital on Oct. 25th, the circumstances being remarkable from the fact that the veterinary evidence tended to negative the hypothesis that the dog suffered from rabies. The deceased was a man, thirty-six years of age, who was bitten on the ear by his pet dog on Aug. 29th. He was at once taken to a medical man, who cauterised the wound, but on Oct. 16th he had a fit and was conveyed to the hospital, where he died the following day. The house surgeon at St. Bartholomew's Hospital stated that at the time of admission the deceased was suffering from fits which were compatible with hydrophobia, and that the case terminated fatally in twenty-four hours. He had made a post-mortem examination and considered that hydrophobia was the cause of death; inoculation experiments had been performed with rabbits, but the results could not be known for some time. Mr. Albert Owen Hughes, M.R.C.V.S., said that he received the dog, a fox terrier, on Aug. 29th, but he saw no symptoms of rabies, "and with a little medicine it appeared well after two days." On the fourth day the witness was asked by the deceased to poison it, after which he made a post-mortem examination and came to the conclusion that the dog was sound. He had also inoculated rabbits, which were still alive. The witness further stated that if the dog was proved to be rabid he would be liable to a penalty for not reporting the case. The body of the dog was afterwards exhumed, and on Sept. 7th it was examined by Professor Bradford, of the Brown Institution, with a negative result. By this time, however, decomposition had set in. Rabbits were also again inoculated, and they were still alive. As the circumstances of the case seem to have afforded every conceivable opportunity for investigating the condition both of the man and the dog, it is much to be regretted that the medical and the veterinary evidence could not have been harmonised. The jury ultimately returned a verdict of death from hydrophobia.

THE Society of Anæsthetists will hold a conversazione at 20, Hanover-square on Thursday, Nov. 18th, commemorative of the fiftieth anniversary of the introduction of chloroform as an anæsthetic. An oration on "Empiricism or Science? Anæsthetics, 1847–1897," will be delivered at 8.30 P.M. by the President, Dr. Dudley W. Buxton. "Smoking," "Music," and "Exhibits" are other items of attraction set forth on the card of invitation.

THE inaugural meeting of the Midland Medical Society was held at the Grand Hotel, Birmingham, on Oct. 22nd, when Sir Richard Thorne Thorne, K.C.B., F.R.S., Principal Medical Officer to the Local Government Board, delivered an important and suggestive address on Soil and Circumstance in their Control of Pathogenic Organisms. This address will appear in an early issue of THE LANCET.

WE have just received the report of the Medical Officer to the Local Government Board, which we shall notice in detail in a future issue. Besides the regular reports the volume contains sundry appendices upon subjects of great scientific interest, amongst others one upon Snake Venom by Dr. Kanthack, and one upon Non-pathogenic Microbes liable to gain access to Food, by Dr. Cautley.

THE opening meeting and exhibition of the Roentgen Society will be held in St. Martin's Town Hall on Nov. 5th, at 8.45 P.M. Professor Sylvanus Thompson, F.R.S., will commence his presidential address at 9 P.M., prior to which all members and visitors are requested to be seated. All communications with regard to the new society may be addressed to Dr. David Walsh, 5, Pump-court, Temple.

THE Duke of Coburg is said to be interesting himself in the concert in aid of the funds of the Charing-cross Hospital, which is to take place on Nov. 19th at the Queen's Hall. Madame Albani's services are already promised, and the *World* suggests the probability of Royalty being again represented in the splendid band of the Royal Amateur Orchestral Society.

PROFESSOR JAMES DEWAR, F.R.S., President of the Chemical Society, will lecture on Thursday, Nov. 4th, at Burlington House, on "The Properties of Liquid Fluorine," "The Liquefaction of Air and the Detection of Impurities,"

Digitized by Google

and "The Absorption of Hydrogen by Palladium at High Temperatures and Pressures."

WE understand that Mr. Joseph Smith, chairman, and Mr. W. G. Dickinson, one of the honorary secretaries, have resigned their positions on that queerly named body the "Corporate and Medical Reform Committee."

THE sum of £1000 has been received for the endowment of a bed in Westminster Hospital in memory of the late William Farmiloe, as a memorial of a lifelong connexion with the city of Westminster.

HOSPITAL REFORM.

THE Earl of STAMFORD presided over a conference which was held on Oct. 21st at St. Martin's Town Hall under the auspices of the Hospital Reform Association.

In opening the proceedings the CHAIRMAN explained that the meeting had been convened to discuss the question of the administration of medical relief in the out-patient and casualty departments of hospitals and dispensaries. There were several societies working side by side, he said, which were working with the same object in view. He himself did not belong to the Hospital Reform Association, but he was an active member of the Charity Organisation Society. As evidence of the urgent need for reform Mr. Garrett Horder had compiled statistics which showed that in the twenty-two general hospitals of London no fewer than 897 000 out-patients were treated, and at the sixty-eight special hospitals 67,500, during the year 1895. When to these were added those treated by non-provident dispensaries the total number of out-patients reached about 1,000,000 of the population of London. A large proportion of these persons were able to pay for medical treatment. The Charity Organisation Society, after inquiry, had come to the conclusion that only about one-quarter of the whole number were suitable recipients of this form of relief, and a grave injustice was done to the general practitioner.

Mr. HORDER then read a short paper on the subject of Medical Reform, in which, after quoting a number of statistics tending to show that the system of out-patient treatment was greatly abused, he entered a plea for a hospital board in towns and expressed the opinion that provident dispensaries might do much to relieve the hospitals of needless work.

Mr. TIMOTHY HOLMES said that at many hospitals practically nearly every applicant received relief, but nothing could be done without the cordial support and coöperation of the profession as a whole. He was glad to see that the association was largely composed of general practitioners. The abolition of existing methods would, he believe, benefit the poor as well as the majority of medical men; but he feared that improvement would be slow, and he exhorted the supporters of the movement to be cautious and temperate in their conduct and language. He proposed the following motion:—

"That this Conference is of opinion that reform is urgently needed in the methods of administering out-patient and casualty relief in the hospitals and infirmaries of the United Kingdom, and that it be referred to the council of the Hospital Reform Association to form a committee to draw up a scheme for the better administration of such relief for the consideration of a future meeting of the Conference."

Dr. GLOVER seconded the resolution, and said that from his experience of the Hospital Sunday Fund he believed that the abuse of hospital relief was not only very large, but the evil was rapidly growing, and ought to be speedily dealt with. The existing system was hard both on the young consultant and the general practitioner. Hospitals were only for unusual cases, and even grave illnesses ought to be treated at home by the family medical man where home conditions were favourable. To effect an improvement they must secure the coöperation of the staffs of hospitals, and that would not be easy, as the out-patients were looked upon as valuable material for medical teaching. The great number, however, made good teaching impossible, and when the medical man had only a minute for each patient slovenly and inaccurate examination was inevitable. The hospital was the place of all others where such work should be thorough and leisurely.

Sir WILLIAM BROADBENT said he approved of the appointment of a committee, but thought that the staffs of the hospitals were powerless to reduce the number of out-patients. The question was really one of right and wrong, and it was a grave evil, for time wasted on slight ailments or undeserving persons was time stolen from the really poor. He could not quite agree that rapid diagnosis was necessarily an evil, as it enabled a man to gain wide experience of ordinary illnesses.

Sir HENRY BURDETT was opposed to the formation of a committee of investigation. A committee, if appointed, should be called upon to devise a new system. There was only one new element in the out-patient question and that was the increase in the number. But one remedy should not be forgotten—private treatment should be made more efficient. Was it not the truth that some hospital cases became so because of incompetent treatment in the early stages of illness by the general practitioner? Why should not post-graduates, men in actual practice, be allowed to visit the hospitals and thereby gain experience and knowledge? Most of the out-patients could pay something, and many of them would welcome the suggestion that they should become regular subscribers to the hospitals. Every hospital should have a registration officer to make proper inquiries as to means and should provide facilities for small subscriptions. He suggested an adjournment of the conference until next year. The subject had been much forced on the attention of the Hospital Sunday Fund and other bodies, especially by Dr. Glover, and he had reason to hope that some practical suggestions would soon be made which would meet the views of the meeting.

Dr. WARD COUSINS believed that the real sufferers by the present system were the charitable public. Hospitals were for urgent cases, not among the poor alone, but among all those who had not proper accommodation at home. People who were unable to pay for exceptional illnesses or accidents should be admitted, but admitted on the recommendation of the family medical man. Dr. Cousins strongly protested against Sir Henry Burdett's view that there was any excuse for the great abuse of the out-patient department in any want of efficiency in private practitioners. He could testify to an enormous improvement in medical education and in the efficiency of the medical profession. The right quarter to which to appeal was the governing bodies and committees of management.

After considerable discussion the motion was carried.

THE INDIAN RISING.

THE fighting on our Indian frontier during the past week has assumed the character of guerilla warfare, but the advance in force must soon take place now. The task imposed upon the Indian Government and the expedition is a more serious and difficult one than many people suppose, and we must make up our minds that the troops will have to encounter a good deal of hardship and hard fighting before it is over. The illustrations in the pictorial papers will give some idea of the great topographical obstacles and mountain passes of the country and an indication of the enormous difficulties of the expedition in the way of marching, transport, water-supply, and commissariat, which will have to be overcome before the force can reach Tirah. The weather is already becoming colder; there are great diurnal variations of temperature, and the troops are bivouacking without tents. The fact that they are reputed to be very healthy and, as we may believe, daily becoming hardier, shows what can be done in mountain air under the excitement of war if only men are well fed and well clad. The cold during the fast approaching winter will be severe and will tell seriously upon the native followers from the plains of India unless great care has been taken about their clothing and food. Native troops suffer a good deal on field service in the hills from pulmonary disease, but the robust little Goorkhas, who come from Nepaul, are not more affected in this respect than Europeans, and the Sikhs and Punjabi regiments, besides being fine, healthy, hardy soldiers, stand the climate fairly well. As might naturally be expected the

Digitized by Google

cold kills the native and the heat kills the European soldier serving in India. If the expeditionary force has to campaign in the mountains and valleys during the winter season a certain number of cases of frost-bite may also be expected to occur. But it may be taken for granted that every effort will be made to push the forces on to their destination before any extreme cold has set in.

We have received from India a copy of the medical arrangements for the Tirah expeditionary force, dealing with the organisation and administration of the hospital service, and including the arrangements provided for corps-units, field and general hospitals, field medical store depots, lines of communication, &c. It consists of a brief pamphlet of eleven pages, issued by Surgeon-Major-General Gore, principal medical officer of Her Majesty's forces, with the approval of H.E. the Commander-in-chief in India. Under the head of organisation it gives the composition of the different brigades of the main and of all the other columns making up the expedition as a whole, with the various sections of field hospitals, British and native, attached to and accompanying the different brigades. We may premise that a Field Service Medical Code was drawn up a few years ago and was issued with the authority of the Government of India in the military department for the information and guidance of everybody concerned, in which everything connected with the subject is fully detailed. This code of regulations, which strikes us as extremely good, is in the hands of all concerned, and medical officers and others are, of course, supposed to be well acquainted with it and to act upon it. The field hospital system in India has been drawn up with special reference to the exigencies of service in that country, although it is based upon the same principles as those of the British service at home and, indeed, of most continental armies. The field hospitals in India are equipped for 100 beds each, and divisible into four sections each complete in itself. These hospitals have distinguishing numbers and the sections are distinguished by letters above the number of the hospital to which they belong. This appears to us a very good and simple arrangement, and capable of making the hospital provision practically adapted to almost any occasion that can arise. To return, however, to the pamphlet under our notice, it lays down the number of hospitals and the sections thereof accompanying the various columns, divisions, and brigades, and those for the lines of communication, together with the general hospitals, British and native, at the base—viz, at Rawal Pindi, Nowshera, and Kohat, for the reception of the sick and wounded coming down from the various forces in the field. These hospitals provide accommodation for about 2000 patients. The principles governing the organisation of a field medical service are pretty well known. Briefly stated they are to provide for the immediate requirements of the force and to relieve it of all non-effectives; to transfer the sick and wounded (trifling cases excepted) in the direction in which they must eventually go—namely, to the base of operations—and to apportion the hospital establishment and equipment to the requirements of the force as a whole. The medical units employed in the operations against the Mohmands are directed to concentrate at Peshawar on the conclusion of that service. It would be impossible, of course, to enumerate the various provisions that have been made, but, speaking generally, the arrangements seem on paper to be very good and to have been well and carefully thought out. The conditions and circumstances of the expedition are of an exceptional character and, we need scarcely add, do not admit of a provision being made on the scale and of the nature employed in European warfare. As regards administration, the following principal medical officers have been appointed:—For the Army Staff: Surgeon-Colonel (with temporary rank of Surgeon-Major-General) G. Thomson, C.B., Indian Medical Service. Secretary: Surgeon-Major W. A. Morris, Army Medical Staff. First Division: Surgeon-Colonel E. Townsend, Army Medical Staff. Second Division: Surgeon-Colonel G. McB. Davis, D.S.O., Indian Medical Service. Line of communications: Brigade-Surgeon-Lieutenant-Colonel (with temporary rank of Surgeon-Colonel) W. E Saunders, A.M.S. Peshawar Column: Brigade-Surgeon-Lieutenant-Colonel R. G. Thomsett, A.M.S. Kurram Movable Column: Brigade-Surgeon-Lieutenant-Colonel W. R. Murphy, D.S.O., I.M.S. The Rawal Pindi Reserve Brigade: While at Rawal Pindi the medical administration will be conducted by the Principal Medical Officer of that district.

METROPOLITAN HOSPITAL SUNDAY FUND.

IN the absence of the Lord Mayor Sir SYDNEY WATERLOW presided over a meeting of the Council of the Metropolitan Hospital Sunday Fund on Wednesday, Oct. 27th, which assembled in the Venetian Parlour of the Mansion House to receive a special report from the Distribution Committee in reference to out-patients.

Sir SYDNEY WATERLOW said he could not commence the business without expressing his own and their deep sense of grief at the loss which Her Majesty the Queen and the nation had sustained by the sudden death of the Duchess of Teck, who had always been ready to assist the cause of charity in every possible way.

Referring to the question of out-patients the Chairman said that twelve months ago the Council inserted a draft paragraph in their report to the constituents of the fund, but when the matter came up for discussion Dr. Glover objected to it on technical grounds stating that it was the duty of the committee to report to the Council, and that upon their report a report should be framed to be put before the constituents. The paragraph was therefore struck out and the matter referred to the Distribution Committee to be considered. For several years the Committee had had their minds very much affected by the discussions about the out-patients' departments of hospitals, and as far back as 1892 they had before them evidence with reference to the matter. Year by year a great deal of fresh information had been obtained, and especially this last year when they had had conferences with the representatives of thirty different hospitals. There was, however, quite a diversity of opinion among the different people from whom they had gained their information. As an example he read replies from some of the large London hospitals and quoted the remarks of speakers at recent meetings on hospital reform. He formally moved the adoption of the following report of the Committee of Distribution:—

The committee of distribution having carefully reviewed all the evidence received by them during the last four or five years in reference to the out-patient departments of the several hospitals, and having recently obtained further information on this important subject, are of opinion that, where no person has been already appointed, efforts should be made to induce the governing bodies of hospitals to appoint efficient persons to make inquiries respecting patients attending out-patient departments with the view of preventing any abuse, and that the Council of the Hospital Sunday Fund should exercise the greatest caution before interfering with the internal management of hospitals.

Mr. F. C. CARR-GOMM said before the adoption of the report was seconded he would like to point out that there did not seem any such diversity of opinion amongst the hospitals as the Chairman had suggested. They did not admit that abuse existed to any great extent.

Sir EDMUND HAY CURRIE, who seconded the motion, said that while the treatment of the in-patients was much improved, no such improvement had been made with regard to the out-patients. This class was chiefly composed of wage-earning people, who were, he believed, ready to pay for treatment if allowed to do so.

Dr. GLOVER suggested that the report be entered upon the minutes. He submitted the following as an alternative motion:—

That the Council of the Hospital Sunday Fund having before it the yearly statistics of the metropolitan hospitals and the report of the Distribution Committee on the out-patient department of hospitals is of opinion that the large and increasing number of out-patients is a matter calling for the anxious attention of the managers of hospitals, and that this council, while disclaiming any wish to interfere with the internal management of hospitals, will look upon the appointment of efficient inquiry officers and other means of curtailment as points of merit in administration.

After some discussion, in which Sir HENRY BURDETT, the Hon. SIDNEY HOLLAND, the Rev. Dr. RIGG, the Rev. Dr. BARLOW, and the Rev. C. H. GRUNDY took part, the CHAIRMAN proposed the following:—

That that this Council recommends that at the next meeting of the constituents in December, the following clause be added to the laws of the constitution: 'That where any hospital having an out-patient department has appointed a special and efficient officer for detecting any abuse in that department, it shall be regarded by the Distribution Committee as an important factor in determining the merits.'

Sir WILLIAM BROADBENT, in seconding the resolution, said that the step which was being taken to-day was a very

Digitized by Google

important one. It would be a very efficient check upon those hospitals which had no attached medical school but which actually competed with those that had for out-patients.

Dr. GLOVER was glad that the Council had taken this step. The very size of the meeting and the patience of its members showed that they were dealing with no ordinary question. Whether the figures relating to the number of out-patients were inaccurate as had been suggested or not the fact remained that the numbers were enormous and what struck him most was that the numbers were increasing. Whereas in 1895 the number of out-patients was 1,098,224. in 1896 they were 1,141 444, or an increase in one year of 43,000 persons. He quoted statistics showing the individual yearly increase in several of the large London hospitals and concluded by stating that the present action of the Council would tend to raise this Fund greatly in the estimation of the public.

The CHAIRMAN stated, in reply to a question by the Rev. M. R. Nelligan, that the attention of ministers of all denominations would be called to the matter in the annual circular issued to them. In answer to Sir Henry Burdett, he also stated on behalf of the Council that there was no desire to reduce the salaries of chaplains of hospitals.

The usual courtesies to the Chairman terminated the proceedings.

FORTY-SIXTH REPORT OF THE INSPECTORS OF LUNATICS, IRELAND.

THE Report commences with the usual summary giving the number and distribution of the insane in establishments on Jan. 1st, 1896, and Jan. 1st, 1897, respectively. This summary shows an increase of the insane under care during 1896 in all the different institutions receiving them, except workhouses, viz., an increase of 709 in district asylums, of 2 in the criminal asylums, of 13 in private licensed houses and institutions for the insane; while the number in workhouses has decreased by 120. The total increase for the year—609—was not so large as that for 1895 (702) but considerably exceeded the average for the past ten years, viz., 405. It is significant that an increase has taken place amongst the cases admitted for the first time to district asylums—the number being 106 in excess of the previous year—an increase in this class which has not been exceeded since 1890. The Inspectors attribute this increase to the transfer of cases from workhouses to asylums, as these cases would be returned as not having been previously under treatment in asylums and they would thus be added to the newly-occurring cases of insanity. It seems that in Ireland there is a large number of pauper lunatics wandering at large or residing with relatives. In the census returns of 1891 their number was estimated to be 4,970. The Inspectors are of opinion that the admissions to district asylums have been largely drafted from this class, and that the number of the insane under care is likely to go on increasing until the existing body of unregistered insanity has been absorbed. Further, they state that it seems certain that the accumulation of the registered insane in asylums has not yet reached its maximum. This is no doubt true, but all the admissions do not come under the category of chronic cases above referred to. An examination of Table V., Appendix A, reveals the startling fact that no less than 42·5 per cent. of the total admissions into district asylums were recent cases of insanity, in which the disease originated within three months of admission. No statistics are given by which a comparison can be made between this percentage and that of past years, but from a table on page 6 of the Report it is abundantly evident that there has been an almost progressive increase in the number of first admissions into district asylums since the year 1880, and that the number of first admissions was higher in 1896 than in any year during this period. In the face of such evidence it is more than probable that the increase of insanity in Ireland is not only apparent but real, and, sad to relate, it is fastening itself on a diminishing population. The Inspectors themselves are uncertain on the point, and cannot determine whether the disease is actually increasing or not. Surely they are in a position to ascertain the exact facts, and so end the uncertainty which exists on the subject. In 1880 the proportion of registered lunatics per 100,000 of the population was 250; at the present time it stands at the high figure of 416 per 100,000 of population.

There are twenty-two district asylums in Ireland. No new asylum was opened during the year; but the Antrim and Portrane Asylums are in course of erection. The admissions into the district asylums numbered 3329. The great majority of the cases were admitted under the provisions of the Act 30 and 31 Vic, cap. 118, s. 10, as dangerous lunatics. The Inspectors regret that this should be so, for the procedure is cumbrous and objectionable, inasmuch as it converts the lunatic into a quasi criminal and places difficulties in the way of obtaining any contribution towards his maintenance, either out of his own property or from his friends. The recoveries in the district asylums numbered 1217, the percentage on admissions being 37·2 as compared with 39·3 in the previous year. The deaths amounted to 926. The rate of mortality was slightly under that of 1895. In only 220 cases were post-mortem examinations made, a number which compares unfavourably with that of the preceding year. Three suicides and three fatal casualties were reported during the past year in district asylums. The small number of such deaths speaks well for the care and supervision exercised in the treatment of the insane in Ireland. On the other hand, overcrowding is general and there is a formidable list of cases of zymotic disease due to insanitary conditions. Allusion is made to the reappearance of beri-beri at the Richmond Asylum, of which so much has been heard of late. The Inspectors as a rule speak favourably of the management of the various district asylums. The Central Criminal Asylum at Dundrum continues to be administered with success. The condition and surroundings of the insane in Irish workhouses leave much to be desired.

THE ENTRIES AT THE METROPOLITAN MEDICAL SCHOOLS, 1897-1898.

THE figures in the following table have been kindly supplied to us by the deans of the various metropolitan schools in response to a circular letter from us asking the number of students who had entered at each school this October session:—

Name of School.	Full medical.	Perpetual.	Partial.	Preliminary scientific.	Special classes.	Occasional.	Dental.	Dental students who have entered medical school.	Total.	Total for session 1896-97.
St. Bartholomew's Hospital	—	97	—	22	69		—	—	188	165
Charing Cross Hospital	21	—	—	—	—	—	20	—	41	74
St. George's Hospital...	49	—	—	—	4	—	—	—	53	37
Guy's Hospital	86	—	—	24	26	—	44	43	223	155
King's College Hospital*...	15	—	—	—	—	—	—	—	15	184
London Hospital... ...	68	—	—	10	47	—	—	—	125	148
St. Mary's Hospital ...	54	—	—	13	61†	—	2	—	130	138
Middlesex Hospital ...	14	—	—	—	—	17	15	—	46	76
St. Thomas's Hospital	53	—	—	10	19		—	—	82	63
University College Hospital	37	—	40	30	—	—	—	—	107	144
Westminster Hospital	9	—	10	—	—	—	—	—	19	23
London School of Medicine for Women*	29	—	—	—	—	—	—	—	29	51

* From King's College Hospital and the London School of Medicine for Women we only received exactly what we asked for—namely, the number of students who had embarked upon a full medical curriculum.

† Not counting men who joined for special classes. Including these the number would be 116.

It will be seen that at St. Bartholomew's Hospital the return is made under the head of "Perpetual Students." The figures in the last two columns of the table show the

Digitized by Google

comparative popularity of the various schools for the last two years as shown by the gross totals; but it is to the figures relating to the students who have entered for the complete curriculum that chief attention will be directed.

A NEW ELECTROLYTICAL APPARATUS FOR THE PRODUCTION OF CAUSTIC SODA.

SOME of our industrial processes seem nearly as clumsy and circuitous as the method employed by the mythical Chinaman for obtaining roasted pig. Of no process is this more true than of our methods for the production of caustic soda and bleaching powder. All that is required theoretically is to separate the two constituents of common salt; to combine the separated sodium with water on the one hand, and the free chlorine with lime on the other. To accomplish this it is necessary in the Leblanc method to heat the salt with sulphuric acid, producing hydrochloric acid and sulphate of soda. The latter material is heated in a revolving furnace with coal dust and chalk, the sodium carbonate produced being extracted from the evil-smelling vat-waste (calcium sulphide) and subjected to tedious purification. To form caustic soda the carbonate of soda must be boiled with lime, whilst the hydrochloric acid produced in the first part of the process has to be treated by the Weldon, Deacon, or other method for the production of chlorine. The vat-waste itself undergoes another process in which the sulphur is recovered. All this to separate the two constituents of common salt! The Solvay or ammonia-soda process performs the operation in a more satisfactory manner as regards the soda, but the whole of the chlorine is lost. The obvious way of overcoming these difficulties is by passing a current of electricity through a solution of common salt, and many inventions have been based on this principle; but, simple as it may seem, the task of breaking up sodium chloride by electricity is exceedingly difficult on the large scale. The two elements recombine, forming complicated secondary products, necessitating the use of a diaphragm to keep the sodium and the chlorine separate. The diaphragm and the electrodes conveying the current are attacked by the nascent materials, and the diaphragm places a great resistance in the path of the current, so that this method does not answer. The Castner-Kellner process, using an electrode of mercury, requires no diaphragm. The sodium is set free at the surface of the mercury and combines with it, forming an amalgam. By means of a rocking motion the mercury is continually circulated, the sodium being converted into caustic soda by contact with water. The latest electrolytic method using Rhodin's Patent Electrolytical Apparatus was demonstrated at the Hôtel Cecil on the 26th inst., and, as far as can be judged from the working of a laboratory model, seems to approach very near perfection, the efficiency claimed being 95 per cent. of the energy consumed. The apparatus is simple and ingenious in the extreme, and there is no obvious reason why it should not work as well on the large as on the small scale. It consists essentially of a flat, circular, iron dish, containing mercury, connected to the negative pole of the dynamo. A smaller, similar, but inverted dish of earthenware, the edge of which passes down into the mercury, divides the vessel into a central inner compartment and an annular outer chamber. In the former is placed a solution of common salt, whilst the latter is occupied by pure water. The earthenware dish carries a number of carbon rods which project down into the brine, these rods being connected to the positive pole of the dynamo. The whole arrangement of inverted earthenware dish and rods revolves, keeping the contents of the vessel, including the mercury, in continual circulation. As the current passes from the carbon to the mercury the sodium carried with it amalgamates with the mercury, which conveys it to the water in the outer compartment, where caustic soda is formed and hydrogen given off, this hydrogen being employed to heat the apparatus nearly to boiling point. The chlorine passes through a pipe in the centre of the earthenware dish and is conveyed to the lime chamber to make bleaching powder. If Rhodin's process becomes a success, as seems probable, not only will the cost of bleaching powder and caustic and washing soda be much reduced, but, by the elimination of older processes with their objectionable concomitants, sanitary conditions will be improved.

THE ELECTION OF A DIRECT REPRESENTATIVE.

WE have received the following letter for publication:—

To the Registered Medical Practitioners of England and Wales.

LADIES AND GENTLEMEN,—Accept my thanks for the support accorded to me at the recent election of a representative on the General Medical Council. I still adhere to the opinion that the general practitioners ought to be represented on the General Medical Council by a general practitioner, and shall be glad on any subsequent occasion to place my services at your disposal.

I remain, your obedient servant,

Winckley-square, Preston, Oct. 25th, 1897. JAMES A RIGBY.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6770 births and 3572 deaths were registered during the week ending Oct. 23rd. The annual rate of mortality in these towns, which had been 16·2 and 16·9 per 1000 in the two preceding weeks, was again 16·9 last week. In London the rate was 16·8 per 1000, while it averaged 17·0 in the thirty-two provincial towns. The lowest rates in these towns were 11·6 in Derby, 11·7 in Plymouth, 12·4 in Gateshead, and 12·5 in Croydon; the highest rates were 20·5 in Liverpool, 20·6 in Bolton, 20·8 in Preston, and 22·7 in Wolverhampton. The 3572 deaths included 429 which were referred to the principal zymotic diseases, against 437 and 415 in the two preceding weeks; of these, 92 resulted from measles, 82 from diarrhœa, 81 from diphtheria, 79 from "fever" (principally enteric), 49 from scarlet fever, and 46 from whooping-cough. No death from any of these diseases was recorded last week either in Croydon or in Halifax; in the other towns they caused the lowest death-rates in Oldham, Bradford, and Gateshead; and the highest rates in Burnley, Preston, Wolverhampton, and Sheffield. The greatest mortality from measles occurred in Wolverhampton, Burnley, and Preston; from scarlet fever in Sheffield; from whooping-cough in Swansea; from "fever" in Derby, Preston, and Sheffield; and from diarrhœa in Bolton, Preston, and Blackburn. The 81 deaths from diphtheria included 55 in London, 5 in Birmingham, 4 in West Ham, and 3 in Liverpool. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last was 3585, against 3677, 3692, and 3725 at the end of the three preceding weeks; 342 new cases were admitted to these hospitals during the week, against 349, 400, and 440 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 176 and 268 in the two preceding weeks, further rose to 279 last week, but were 29 below the corrected average. The causes of 45, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Bradford, Leeds, and in nineteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·8 and 19·1 per 1000 in the two preceding weeks, rose again to 20·3 during the week ending Oct. 23rd, and exceeded by 3·4 per 1000 the mean rate during the same period in the thirty-three large English towns.

Digitized by Google

The rates in the eight Scotch towns ranged from 13·3 in Paisley and 15·3 in Perth to 24·5 in Greenock and 24·6 in Dundee. The 604 deaths in these towns included 29 which were referred to diarrhœa, 27 to whooping-cough, 13 to "fever," 7 to measles, 6 to diphtheria, and 4 to scarlet fever. In all, 86 deaths resulted from these principal zymotic diseases, against 73 and 84 in the two preceding weeks. These 86 deaths were equal to an annual rate of 2·9 per 1000, which was 0·9 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had had been 12 and 20 in the two preceding weeks, further rose to 27 last week, of which 17 occurred in Glasgow and 3 in Greenock. The deaths referred to different forms of "fever," which had been 12 and 6 in the two preceding weeks, rose again to 13 last week, of which 10 were registered in Glasgow and 2 in Edinburgh. The 7 fatal cases of measles showed a slight further increase upon those recorded in recent weeks, and included 5 in Glasgow and 2 in Greenock. The 6 deaths from diphtheria corresponded with the number registered in the preceding week, and included 3 in Glasgow and 3 in Dundee. The fatal cases of scarlet fever, which had increased from 5 to 17 in the three preceding weeks, declined to 4 last week, of which 3 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 162 and 122 in the two preceding weeks, rose again to 144 last week, and exceeded by 28 the number in the corresponding period of last year. The causes of 28, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·9 and 24·0 per 1000 in the two preceding weeks, declined again to 21·2 during the week ending Oct. 23rd. During the past three weeks of the current quarter the death-rate in the city has averaged 22·4 per 1000, the rate during the same period being 16·1 in London and 19·0 in Edinburgh. The 142 deaths registered in Dublin during the week under notice showed a decline of 19 from the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against numbers declining from 39 to 14 in the four preceding weeks; of these, 6 resulted from "fever," 2 from scarlet fever, 2 from diarrhœa, 1 from measles, 1 from diphtheria, and 1 from whooping-cough. These 13 deaths were equal to an annual rate of 1·9 per 1000, the zymotic death-rate during the same period being 2·2 in London and 1·2 in Edinburgh. The deaths referred to different forms of "fever," which had been 4 and 7 in the two preceding weeks, declined to 6 last week. The fatal cases of scarlet fever, which had been 3 and 1 in the two preceding weeks, rose again to 2 last week. The mortality from diphtheria and from diarrhœa showed a decline from that recorded in the preceding week. The 142 deaths in Dublin last week included 30 of infants under one year of age and 25 of persons aged upwards of sixty years; the deaths of infants showed a slight increase, while those of elderly persons showed a further decline from recent weekly numbers. Four inquest cases and 3 deaths from violence were registered; and 40, or nearly a third, of the deaths occurred in public institutions. The causes of 18, or nearly 13 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR CROFTS has been selected for service in West Africa. Surgeon-Major Maunsell is ordered for service in India. Surgeon-Major Mitchell takes over the charge of the Station Hospital, Newcastle-on-Tyne, relieving Surgeon-Major Dixon. Surgeon-Lieutenant L. A. Ward has embarked for Bombay. Surgeon-Major J. S. Green has embarked for Bombay in the *Dunera* at Queenstown. Surgeon-Captain B. J. Inniss has been placed under orders for service in India.

Brigade-Surgeon-Lieutenant-Colonel Robert C. Eaton to be Surgeon-Colonel, Supernumerary to the Establishment, such promotion to carry no increased pay or allowances prior to the date on which he will be absorbed.

INDIA AND THE INDIAN MEDICAL SERVICE.

The Queen has approved of the following promotions among the Officers of the Indian Medical Service:—Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels:—Bengal Establishment: John Scully and Adam Scott Reid. Madras Establishment: Preo Nath Mookerjee. Bombay Establishment: Matthew Lorenz Bartholomeusz. Surgeon-Lieutenants to be Surgeon-Captains:—Bengal Establishment: George Ramsay, David Waters Sutherland, William Selby, Thomas Arthur Granger, Harold John Kinahan Bamfield, John Wemyss Grant, Arthur Henry Moorhead, William Davey Hayward, Archibald William Forbes Russell, and William Elmsley Scott-Moncrieff. Madras Establishment: Charles Ross Pearce. Bombay Establishment: Vivian Boase Bennett, Hugh Myddleton Moore, and Dudley Cater Johnston.

The Queen has approved of the retirement from the Service of the under-mentioned Officers:—Surgeon-Colonel George Cumberland Ross, Bengal Establishment; and Surgeon-Colonel David Erskine Hughes, Bombay Establishment.

NAVAL MEDICAL SERVICE.

The following appointments have been notified:—Fleet Surgeon Alfred Patterson to the *Royal Arthur*. Staff Surgeons: William H. Norman to the *Venus*; William G. Jack to the *Hood*; and George A. Dreaper to the *Magicienne*. Surgeons: Rowland A. Kirby and Hugh P. Turnbull to the *Royal Arthur*; H. E. Tomlinson to the *Rambler*; John C. Ferguson to the *Cambridge*; Albert X. Lavertine to the *Ringdove*; William D. Andrews to the *Venus*; Matthew J. O'Regan to the *Alert*; Walter Bowden D.S.O., to the *Victory*: Ernest S. Tuck to the *Esk*; George Wilson, M.B., to the R.M.A. Eastney, Hilary C. Arathoon to the *Thrush*; Frederick A. Brice to the *Champion*; and Henry J. Hadden to the *Thunderer*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain E. Jones, having retired from the Volunteers, ceases to belong to the Army Medical Reserve of Officers; Surgeon-Captain E. T. Crouch to be Surgeon-Major; Surgeon-Lieutenant Richard Harman Luce, 1st Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment), to be Surgeon-Lieutenant.

VOLUNTEER CORPS

Rifle: 1st Volunteer Battalion the East Yorkshire Regiment: Surgeon-Lieutenant H. G. Falkner to be Surgeon-Captain. 2nd (Earl of Chester's) Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant T. J. Selby resigns his commission.

THE ARMY VETERINARY DEPARTMENT.

We have received the Annual Statistical and General Report, drawn up by the Director General (Veterinary-Colonel Duck), of the Army Veterinary Department for the year ending March 31st, 1897. According to the details mentioned the total number of animals on the home strength was 13,386 troop horses, 109 mules, and 1796 chargers, being slightly less than that of last year; the amount of inefficiency was 61·10 per cent., as compared with 60·01 last year and 67·35 in 1894. The number of deaths was 332, or 2·52 per cent. of the average strength, this proportion also being slightly in excess of those of previous years. Of the animals admitted into the infirmary the larger proportion were, as usual, taken in on account of surgical diseases and injuries; there being an increase over the number of last year in the animals suffering from diseases of the chest and air passages, and also amongst those admitted for general diseases. It is especially gratifying to find that there has been no sign of the reappearance of glanders either at home or in Egypt, and that a slight outbreak with the troops in Matabeleland was speedily stamped out owing to the energetic measures employed. This outbreak was confined to one case only, and no further sign of its spread having occurred has appeared. At the Army Veterinary School, Aldershot, the usual classes have been held for officers and farriers, the attendances and number of those presenting themselves for examination showing that both officers and men took great interest in the work done. The Vaccine Institute still maintains its reputation under the management of Veterinary-Major Longhurst and Veterinary-Captain Butler, the number of persons for whom lymph was cultivated during the year being 44,451. Since the opening

Digitized by Google

of the institute in January, 1889, lymph has been prepared for 335,047 persons. During the past year the percentage of successes with primary vaccinations was 96·59, and of re-vaccinations 89·40; in the foreign stations the percentage of successes was 82·37 with primary vaccinations, and of re-vaccinations 75·59. Seventeen calves were vaccinated during the year, thus giving an average of 2614·76 persons to each animal. The report concludes with the various diseases arranged in tabular form, and a list showing both the causes for selling the cast animals and the average length of service.

THE NILE EXPEDITION.

There has not been much to chronicle of late in connexion with the Soudan expedition. Little or no fighting has recently taken place, and the Sirdar (General Kitchener) has usually managed to keep all matters connected with his intentions and the operations of the expedition to himself. The most important work that has been carried on has been the construction of the railway which is to be run on to Berber. This will have a very favourable effect on the trade and commerce of the Soudan. There has been a successful gunboat reconnaissance to Metemmeh with the view of inspecting the Dervish camp and fortifications works. The rule of the Dervishes has been a very cruel and tyrannical one, and the Soudanese population which have been subjected to it have everywhere welcomed the arrival of the Egyptian force. The Egyptian troops are healthy, and the medical service has had of late but little to do, but the heat and monotony of the life have proved trying. The progress of the expedition has been slow but sure so far, and it looks as if no military advance or undertaking of importance was imminent at the present moment.

DEATHS IN THE SERVICES.

Surgeon-General William Robert Cornish, I.M.S., C.I.E., F.R.C.S. Eng., Honorary Physician to the Queen and late of the Madras Army, on the 19th inst., at Worthing, in his seventieth year. The deceased officer received his medical education at St. George's Hospital, where he won, among other prizes, Sir Benjamin Brodie's gold medal for clinical surgery and subsequently was appointed to the East India Company's Medical Service as an assistant surgeon of the Madras Army in 1854. After holding various appointments he became secretary to the Director-General of the Medical Department in 1860. After holding that post for nearly ten years he was appointed sanitary commissioner to the Madras Government. In this appointment he rendered excellent service during the famine in Southern India in 1877, for which he received the C.I E. In 1880 he became Surgeon-General of the Medical Department, and retired in 1885, when he was made an Honorary Physician to the Queen. Among his contributions may be mentioned "The Madras Census for 1871," "Prison Dietaries and Food," "Typhoid Fever in the Madras Presidency," "The Cleansing of Indian Towns," and the various annual reports on the causes of deaths in the Madras Presidency. The deceased officer also served for a time as a member of the Legislative Council at Madras, and helped to frame the present Local Government Bill of that presidency. He also assisted in compiling the Famine Code, The late Surgeon-General Cornish was an energetic and able officer of considerable ability and much respected.

Brigade-Surgeon John Kinahan, M.D. St. And., A.M.S., retired list, on the 30th ult., at Southsea, aged sixty years. He had long service at home, in India, China, Canada, the Mediterranean, and finally went through the Egyptian campaign of 1882 (Medal and Khedive's Star), afterwards taking part in the Nile expedition, from which he was invalided home after undergoing great hardships in the course of his arduous duties. He was universally liked and respected.

Surgeon-Major Thomas Allman Wethered, retired list, Bengal Army, at Paris, on the 17th inst., aged eighty-three years.

THE PHYSICAL STANDARD FOR CANDIDATES FOR ARMY COMMISSIONS.

We are glad to notice in the public journals an announcement on official authority which is very closely in accordance with the tenor of the article published in THE LANCET last week on this subject. The scale of physical equivalents is laid down for the general guidance of the examining medical board and not as a standard from which no departure is allowed. The medical board can exercise a discretionary power, subject to the approval of the War Office, in relaxing these requirements, and there is no reason why an otherwise eligible candidate should be rejected because he does not at the time of his examination fulfil these requirements—in regard to weight for example.

Correspondence.

"Audi alteram partem."

HOSPITAL REFORM.

To the Editors of THE LANCET.

SIRS,—I have the honour to inform you that a meeting of the medical profession and of others interested in the administration of the medical charities of Brighton and district will be held at the Athenæum, North-street, Brighton, on Friday, Nov. 5th, at 8.30 P.M., to discuss the best means of promoting Hospital Reform. Sir Joseph Ewart, M.D. St. And., F.R.C.P. Lond., has kindly consented to take the chair.

It may interest you to know that my association has made the following recommendations for the prevention of abuse in the out-patient and casualty departments of hospitals: (1) The abolition of subscribers' letters; (2) the limitation of the number of new patients to be seen by each medical officer; (3) the restrictions of out-patients to cases recommended by medical men; and (4) the casualty department to be limited to the reception of urgent cases of illness.

It will be within your recollection that my association convened a meeting of the medical men practising in Manchester and the surrounding district on May 25th last, when the following resolution was duly passed:

> That in the opinion of this meeting the time has arrived when an inquiry should be made into the mode of administering medical relief in the Manchester and Salford hospitals and dispensaries; and it is further of opinion that such an inquiry should be conducted by a committee which should be representative of all the interests concerned.

I now hear from Dr. E. Vipont Brown (who has been acting as honorary secretary) that such a committee has been duly constituted and will hold its first meeting on Wednesday, Nov. 10th. My association and THE LANCET have done their part and it must now rest with the local men to produce reliable evidence before this committee and to express their views as to the best means of improving the present system of medical relief.

Believe me, Sirs, faithfully yours,

T. GARRETT HORDER,

Honorary Secretary to the Hospital Reform Association.

Oct. 27th, 1897.

To the Editors of THE LANCET.

SIRS,—At the meeting of the Hospital Reform Association on the 21st inst., the Earl of Stamford, who was in the chair, brought forward figures showing that the persons annually receiving gratuitous medical relief in the metropolis only amounted to 1,000,000 in number, a total ascertained by taking only the out-patient figures from the various hospital reports. Roughly speaking, this means that from one-fifth to one-fourth of the whole metropolitan population obtains, by the assumption or allegation of poverty, free access to the medical charities primarily designed to help the deserving poor. These, however, cannot constitute more than a small part of this immense total, and the remainder are able to pay for the attendance they require, though evidently not unwilling to accept it as a charity so long as they can have it for the asking. These figures demonstrate a degree of pauperisation which it is terrible to contemplate, but one of the speakers at the meeting showed that there is a still lower depth of demoralisation. This speaker gravely advanced the monstrous proposal that persons who choose to represent themselves as "supporters of the hospitals" should, by paying some trivial amount—half-a-crown was the lowest annual subscription he mentioned—be provided with some kind of ticket *in evidence of their title to relief on demand*. In plain language this means that the poor are to be utterly thrust out of their medical charities in order that the hospitals may be reduced to the condition of vast medical aid associations, and that the already pauperised mass of well-to-do patients shall be enabled to buy, for a contemptible price, those medical

Digitized by Google

services which they now, at any rate, can only obtain as a free gift, and by affecting or asserting a totally fictitious poverty.

There is already abroad, even among those whom one would expect to have clearer ideas, an extraordinary notion that money which they profess to give freely to the service of destitution can also at the same time purchase for them a valuable consideration which is actually itself of far higher monetary worth, and this idea is in many cases pushed to an extreme of meanness barely credible. This new suggestion is the very apotheosis of that "letter-system" which has been largely responsible in fostering this spirit of astute philanthropy, and is already utterly discredited. Once adopt in any disguise the principle that any payment, great or small, secures a right to use the hospital, directly or indirectly, for the benefit of the person making the payment, and the transaction loses its charity and becomes an insurance. Practically this plan would result in two certain consequences—the benevolent would find some better object for their attention, and the work of the hospitals would become so enormously enlarged that these institutions would be forced bodily upon the rates, a socialistic experiment for which we are as yet, perhaps, hardly prepared.

I am, Sirs, yours faithfully,

Oct. 25th, 1897. H. H.

"BERI-BERI AND ERRONEOUS DIAGNOSES."

To the Editors of THE LANCET.

SIRS,—In an introductory lecture at St. George's Hospital Dr. Patrick Manson gives a long list of erroneous diagnoses as transcribed verbatim from the register of the Seamen's Hospital. In the list are anasarca, rheumatism, debility, pericarditis and fits, apoplexy, locomotor ataxia, myelitis, paraplegia, tachycardia, dyspnœa, cardiac diseases, asthma and anasarca, Bright's disease, progressive muscular atrophy, and hysteria. In answer to my inquiry, Dr. Manson has informed me that they are really taken from the register of the Branch Seamen's Hospital at the Royal Albert and Victoria Docks; and he asks me, if my experience does not agree with his, that I should publish it. This branch hospital contains eighteen beds, and his vague use without qualification of the term "seamen's hospital," has led members of the profession to suppose that he is referring to this institution with its 235 beds. I can find no such errors in our register, for at the worst they are merely incomplete diagnoses, giving a prominent symptom as sufficient for admission—e.g., dropsy, œdema of legs, loss of power in legs, anæmia and œdema, &c. We have admitted eighty-seven cases in the past four years. I would add that all the medical certificates, both at the branch and at this hospital, only come from the medical officers of one of our largest shipping companies.

It is because there is such a wide discrepancy between the experience at the two hospitals that I ask you to make this correction.—I am, Sirs, yours truly,

JOHN CURNOW, M.D., F.R.C P. Lond.

Seamen's Hospital Society *(Dreadnought)*, Greenwich, S.E., Oct. 27th, 1897.

"THE POLICE AND FIRST AID."

To the Editors of THE LANCET.

SIRS,—With reference to a paragraph under the above heading from your Manchester correspondent in THE LANCET of Oct. 16th, although in very few police forces is the number of members holding the certificate of the St. John Ambulance Association greater than in Manchester, in many instances the percentage is higher. Much importance is attached by the Home Office, which requires an annual return of certificate holders, to the instruction of the police in rendering first aid "to the injured," and some interesting statistics in connexion therewith will be published in the first number of the *St. John's Magazine*, the official organ of the Order of St. John and its departments, which will appear on Jan. 1st next.

I am, Sirs, your obedient servant,

HERBERT C. PERROTT,
Chief Secretary, St. John Ambulance Association.

John' Gate, Clerkenwell, E.C., Oct. 21st, 1897.

THE PREVALENCE OF TYPHOID FEVER IN THE AUTUMN.

To the Editors of THE LANCET.

SIRS,—The autumnal season of the year is always of interest to medical men, as it is at this period in general we may expect an outbreak of typhoid fever to occur, and this year must be of especial interest, with the serious state of things existing at Maidstone; therefore it is a duty we owe to each other to render what aid we can to limit the spread of such disease or to point out any source of danger to be avoided for future years. I should like therefore to call the attention of my professional brethren to the games of the young, some of which I believe to be a great source of typhoid and scarlet fevers. I was for some time puzzled to know why boys should present more cases of typhoid fever than girls. The reason is not far to seek if we study the games themselves, especially in large towns, such as Sheffield, where that most abominable and insanitary arrangement of ash middens exists, and where the excrement from such places is simply shovelled out into the streets into large heaps, afterwards to be carted away, but leaving a considerable amount of excrement stinking for days lodged amongst the stones of the road, amongst which boys play at marbles, licking their fingers to prevent the marble from slipping whilst shooting from the hand, with the result that the germs of the disease are directly swallowed, and in no small quantities. Peg-top is also a prolific source of danger, for the whipcord used is drawn through the mouth to wet it and so prevent slipping; after the top is spun it is either thrown down or left dragging in the dirt until again used. These games affect boys and not girls, hence the difference in the numbers attacked in each sex, girls not as a rule playing at such games, which are usually on the go in autumn after cricket is over. Some weeks ago I saw a boy with typhoid fever and was asked by his parents how I accounted for his having it, as there was no case in the same street. I therefore asked his mother to let me see the trousers worn by the boy, and showed her how stinking the pockets were; they also contained marbles, &c., and dirt from the street. These games, to my mind, are a great source of danger to children living a town life. But how to remedy the evil is not very easy whilst such an abominable way of dealing with refuse is allowed to go on. I have pointed out this source of danger to the young, as I have not as yet seen any mention of games in any paper or book. Contaminated water, I much fear, is not the only source of typhoid fever, scarlet fever, &c.—I am, Sirs, yours truly,

W. SKINNER, L.R.C.P., Lond., M.R.C.S. Eng.

Sheffield, Oct. 21st, 1897.

"IMMORALITY AMONG SCHOOL BOYS."

To the Editors of THE LANCET.

SIRS,—Dr. Hime's article in THE LANCET of Sept. 4th has been worthily followed by a letter published on Oct. 2nd from "The Medical Officer to a Public School," who speaks of preparing a pamphlet to be put into the hands of every public schoolboy. This may be one of the best preventives, but is this not a subject which could be authoritatively dealt with by the Society of Medical Officers of Schools? One would not like to think that this society confined its usefulness to merely physical ailments. No other body of men is in such friendly contact with both parents and schoolmasters, and there are many details which might be settled by conjoint wisdom. What, for instance, is the average age when a boy is tempted to put forth his hand and eat of the tree of the knowledge of good and evil? Rev. the Hon. E. Lyttelton tell us in "Mothers and Sons" that the battle begins after the age of fourteen and a half years, and that impurity in a school takes its rise and receives its impetus from boys of fifteen or sixteen years of age who have a constitutional propensity to it and whose wills are feebly developed. Is this the experience of others? The suggestion that meat and alcohol are harmful at supper might be confirmed perhaps. There are many other points on which the utterance of medical experts would be useful, such as cubicles, circumcision, school library books, games, &c.

I am, Sirs, yours faithfully,

Cairo. F. M. SANDWITH, M.D. Durh.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

XIII.—SOUTHAMPTON.[1]

Harmony in the Ranks of the Profession.—A "Free" Hospital where the Patients Pay.—Overwork and Under-pay at the Dispensary.—The Eye Hospitals and the General Hospital.—Cases of Abuse.—Application of a Wage Limit.

THE position of the medical practitioners in the town of Southampton at the present moment is very favourable to the formation of a strong union. The only thing, perhaps, that is wanting is a strong man to take the lead. That, indeed, is one of the main difficulties of all such movements. The two or three practitioners whose position, reputation, and influence are such as to mark them out as the natural local leaders of the profession are very often too much occupied or perhaps too aged to move actively in the matter. Others, it must be confessed, are too comfortable in the enjoyment of a good position to sacrifice their peace of mind and quiet by assuming the responsibilities and encountering the worries that befall organisers and initiators of a movement. But in Southampton these troubles should be comparatively slight, at least at first, for, in contrast to so many other towns, the members of the profession are wonderfully united. There are no feuds between them A grievance has arisen, and it has served the good purpose of showing how closely allied in spirit are the forty or so medical men who practise in Southampton. It is not part of the present subject to deal in full with that grievance. Besides, in THE LANCET of Oct. 20th, 1894, some details are given. They relate to the so-called "Women's Free Hospital for Special Diseases." The number of operations and the result of these operations were unfavourably criticised. The method of electing the committee of the hospital, the absence for a considerable time of a chairman, and many other circumstances all seemed most irregular; but these questions are not intimately connected with the present inquiry. The main point on which I wish to lay stress is not the grievance in itself, but the fact that it brought the members of the profession together and showed that great harmony of feeling existed between them. Nevertheless, there is one phase of this grievance which does concern the present investigation—namely, its economic side. Mr. J. F. Bullar read a paper before the Southampton Medical Society in November, 1894, giving full details concerning the Southampton Women's Free Hospital. From this communication it would appear that though the first report of the hospital acknowledges that the work was commenced in November, 1889, nevertheless no printed report was issued till May, 1892. The earlier reports, that is, up to 1894, make no mention of any meeting of subscribers or of rules for election of the committee of management. Mr. Bullar in his paper says: "It appears, from absence of any statement to the contrary, that the committee originally elected itself and has continued to do so since, and that what is referred to as the 'establishment of the hospital' began and ended in the hiring of a house. The individual members of the committee and of the medical staff appear to be unhindered by any rules from taking what view they please of their responsibilities and of the situation generally, and I was recently assured by a member of the committee that the hospital was the out-patients' department and he utterly repudiated all responsibility for the in-patients." The honorary secretary had admitted that he had not access to the books in a manner that showed a want of responsibility on his part for the in-patients, yet the first report issued by the hospital authorities states that "a ward has been efficiently fitted up at the expense of Miss Pickard with all modern appliances for the reception of in-patients." After describing a futile effort to get a copy of the rules Mr. Bullar expressed the opinion that there were "no rules relating to the constitution and government of the hospital, and that it is even a matter of doubt whether the in-patient department is a public charity or a form of private practice which the committee take upon themselves to recommend to the public."

This last sentence brings us to the economic phase of the question, for it is surely most necessary to see that a charity is not converted into a hunting ground for private patients. Mr. Bullar then went on to say:—

"To understand this arrangement we must turn to the balance-sheets. There we see that the committee derived their income from subscriptions, donations, collections, and such like, and that among other expenses they paid the rent and the taxes of the house used as a hospital. They received no rent from Mr. Eliot on account of the rooms he furnished for his private patients, but paid it for him out of the funds of the charity. There is no mention in the accounts of any payment of £2 2*s.* a week for the in-patients, and therefore as the arrangement 'answered well' it is to be inferred that the patients themselves provided the money for their treatment in the Free Hospital. In the absence of any accounts it is impossible to tell whether Mr. Eliot lost or gained by having the rooms rent free for his private patients and receiving two guineas a week for the hospital patients, but it is quite evident that the term 'free' is inapplicable to the hospital. In the last report the committee state that 'as far as possible patients are encouraged to pay a sum, however small, per week to go towards their actual expenses,' and the medical officer states: 'A good many patients have gladly contributed a small weekly sum.' But in the balance-sheet no mention of the sums or of the 'actual expenses' of the in-patients is made. It appears that when any patient comes to the out-patient rooms in Portland-terrace the medical officer decides whether she ought to be an in-patient, and if he thinks she ought the committee hand her over to the medical officer for treatment at his private house on an understanding that she is to pay to him personally as much as she can up to two guineas per week. They then cease to inquire or trouble themselves about her or to feel any responsibility in the matter, quite ignoring the fact that if they had not written favourable reports of the hospital and called it free the patient would probably never have applied for treatment in Portland-terrace."

Such was the economic side of the grievance which served to rally the medical practitioners of Southampton and triumphantly demonstrated the great unity of feeling that prevailed among them. This agitation brought about some alterations in the management of this so-called free hospital. I have now before me the sixth annual report published in 1896, and here are set forth rules by which the hospital is governed. The first notable change is that the word 'free' has been dropped, for rule No. 1 says: "That the charity be called the 'Women's Hospital.'" The next article deals with the election of medical officers by the committee and their qualifications. Article 5 stipulates that the charity shall be governed by a committee of management consisting of the chairman, treasurer, secretary, medical officers, and fifteen subscribers to be annually elected by all subscribers of 10*s.* 6*d.* and upwards. This committee is to meet quarterly and a general meeting of all subscribers is to be held annually. Patients are to be admitted by letters of recommendation, and subscribers of £1 1*s.* a year are entitled to seven such letters. Subscribers of 10*s.* have three such letters, and one letter is given in exchange for the modest subscription of 5*s.* The position of in-patients, which was formerly so vague as to be almost incomprehensible, is now clearly defined by rule No. 12, and is as follows: "That the committee of management of the hospital shall pay Dr. Eliot £2 2*s.* per week for each bed when occupied, as the hospital has no in-patients' department of its own. Any money that the patient may be able to pay, or that is paid on behalf of a patient, to be put to the credit of the 'Women's Hospital.'" Turning from the rule to the report we find that during the year 1896 there were 107 new cases, giving a total number of 951 attendances treated as out patients. Then it is stated that "the number of in-patients has dropped to fourteen. This is mainly due to lack of funds which prevented us taking in some cases which would have derived great benefit from rest and

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *concluded*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *concluded*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; (6) Feb. 6th, 1897, Leeds; (6 *concluded*) Feb. 13th, 1897, Leeds; (7) April 17th, 1897, Coventry; (8) May 1st, 1897, The Royal London Ophthalmic Hospital; (9) May 8th, 1897, France, United Action and Legislative Action; (10) May 15th, 1897, Leicester; (11) June 5th, 1897, Nottingham; (12) July 31st, 1897, Birmingham; (12 *continued*) Aug. 14th, 1897, Birmingham; (12 *continued*) Sept. 4th, 1897, Birmingham; and 12 (*continued*) Sept. 18th, 1897, Birmingham.

Digitized by Google

nursing." The balance-sheet makes no mention of the payments, if any, made by these fourteen patients. Nor on the expenditure side is there any mention made of the £2 2*s.* per week which presumedly were paid for these fourteen patients. Indeed, the income, due mainly to collections and subscriptions, amounted to only £152 17*s.* 2*d.*, and the principal expenditure was £113 0*s.* 2*d.* for drugs and dispensing. Perhaps, however, Rule No. 12 is no longer applied in full, for in another part of the report the following passage occurs: "Owing to an alteration in the management of Rockstone House the committee have made arrangements with the manageress, Sister Hammond, for patients to be received as in-patients to that institution upon very advantageous terms. Owing, however, to lack of funds the committee have been unable at times to send out-patients as in-patients." Thus the fourteen in-patients may have cost less than £2 2*s.* a week. Still, the report does not explain who paid this cost, whatever it may have been.

That abuses may creep in where the accounts given are so vague and incomplete must be obvious to everyone. It is true that there is a passage in the report which says: "We take this opportunity of asking all who give out-patients letters to try, as far as possible, to give them only to deserving poor women who are suffering from some trouble peculiar to their sex." But then if this recommendation was strictly observed, and the patients were really poor, it becomes still more difficult to explain how the cost of their maintenance as in-patients was met. All this surely suggests the necessity of something more than an amateur inquiry, and this is a point on which several medical men at Southampton strongly insisted. What, they asked me, is to be done when the members of the profession in any locality believe that an investigation into the management of a hospital is necessary? There is no authority entitled to make such an inquiry. The English law, the British Government, provides no machinery for this purpose. A few clergymen, a few benevolent ladies, can block the way to any such investigation. If patients are attracted to a hospital under the impression that it is a charity and are then made to pay, is this not an indirect method of advertisement contrary to professional rules? So far as the Women's Hospital of Southampton is concerned I found that the chairman of the committee of management (the Rev. A. F. Forbes) was far from entertaining any suspicion of this commercial aspect of the case. Instead of making any profit out of paying patients he explained that the medical officer, Mr. Eliot, undertook to pay out of his private resources the difference of cost between what was charged for the maintenance of an in-patient and what the hospital committee could afford to pay for that purpose. He was therefore under the impression that the hospital owed a great deal to their medical officer and were financially in his debt. This evidence as to the disinterested conduct of the medical officer does not, however, effect the principle at stake. If the result of the application of Rule 12 quoted above has not been of financial benefit to the medical officer, or to the home where the in-patients are received, this is not the fault of the rule, but of other circumstances. With such a rule, what at first sight appears to be a charity may well be converted into a commercial enterprise. This therefore constitutes a genuine hospital abuse, against which the members of the profession at Southampton, and Mr. Bullar in particular, did well to protest. Mr. Ingalton Saunders, honorary secretary of the committee of management of the Southampton Women's Hospital, seemed to have a clearer perception of the position, for in answer to my questions he very emphatically declared that the home where in-patients were received was absolutely a distinct institution. The connexion between the Women's Hospital and the home had been broken off. If an operation was deemed necessary the committee of the hospital decided whether they could afford to pay for the patient, and, if so, sent her to the home. Doubtless the home and the hospital are now quite separate institutions. This, however, does not prevent the fact that the hospital is still, to some extent at least, a recruiting ground for the home, and yet the hospital and its committee cannot exercise any control over the home, since they repudiate the home and qualify it as a separate institution. The patient, however, is not likely to make these subtle distinctions. The Women's Hospital is recommended to her in preference to the General Hospital because it is a special hospital, and the names of the medical officers, the patrons, and committee of management inspire confidence. The patient therefore obtains a letter of recommendation, but finds she cannot be treated as an out-patient and is therefore recommended to go to the home and is asked to pay for her maintenance. Naturally she concludes that this is quite a normal proceeding and that the home is part and parcel of the hospital to which she has applied. Doubtless the home is admirably managed and the patient is highly gratified by the treatment she there receives; but if the reverse were the case the committee of the hospital would be blamed for that over which they have no control. Besides, why should a hospital recommend one particular home? Such cases could be treated elsewhere. The thing is wrong in principle, though in this particular instance it may in practice work satisfactorily; but still, if the principle is admitted there is no limit to the abuses that may result.

The members of the profession at Southampton having been brought together by the necessity of dealing with the question of this women's hospital, also took action with regard to other matters. In April, 1894, Sir Dyce Duckworth went to Southampton and read a paper on the Relations of Medical Advisers to Provident Clubs and Medical Aid Associations. A circular was then issued, and thirty-seven Southampton practitioners signed a declaration to the effect that: "(1) club doctors are underpaid for their work; (2) that an increase of payment would benefit the club members as well as the doctors." In Southampton and the adjoining districts of Shirley and Portswood there were at that time 38 medical practitioners. Questions were addressed to all these gentlemen, and answers received from 33. These replies showed that there were 2353 members of private clubs organised by the medical men themselves; 7196 members of the Foresters, Oddfellows, and other benefit societies; and 2203 members of medical aid associations, giving a total of 11,752. Then the Southampton Dispensary had 5808 provident members and 1712 recommended, that is to say, charity, patients. The Poor-law medical officers' returns indicate that they had 1065 indoor pauper patients and 3315 outdoor patients. Thus out of a population of about 80,000 no less than 23,644 were shown to be receiving medical attendance either for nothing or at most for an annual subscription that was often less than 4*s.*, and rarely more. It was satisfactorily proved that many of these patients could have paid the usual fees. The committee appointed by the medical profession of Southampton in the year 1894 to inquire into the matter reported that during the course of the year there were 5800 provident—that is, paying—members of the Southampton Dispensary, and they happened between them to be ill no less than 8117 times in the course of the twelve months. In attending these cases the medical officers had to make 4769 visits to the patients at their own homes and there were 12,861 attendances at the surgery of the dispensary. But if we add those patients who went with letters of recommendation, and who therefore did not themselves pay anything, there was a grand total of 10,324 cases of illness among 7512 patients. These patients were seen about 27,000 times, and the medical officers had by night and day to pay some 8000 visits to the homes of the patients. This involved travelling over several thousand miles, and for this immense amount of work they received between them the munificent sum of £575, or about 1*s.* 5*d.* for each case of illness. As the report very truly observed, few of these patients worked so hard for so little pay. Now as subscribers can send seven patients for 1 guinea this amounts to only 3*s.* per case; but there is a rule to the effect that no medical officer shall receive more than 2*s.* per case. Thus the medical men are obliged to attend perhaps for weeks on a patient, and yet cannot receive more than 2*s* unless the illness lasts more than two months. It would perhaps be better if the medical man received nothing at all, for he would then meet with an amount of consideration he does not now enjoy.

Speaking to one of the local practitioners who had taken an active part in this investigation I found that, in his opinion, a strenuous effort ought to be made to revolutionise the British Medical Association. He did not object to forming a local union of medical men, but did not see who could take the lead in such a movement; therefore it might be easier to utilise the British Medical Association as it was an organisation already in existence. Portsmouth was the local centre of the Association, and in this district there were some 300 members, yet at the annual local meeting only about 40 out of the 300 members attended. This annual meeting elected its representative on the General Council of the Association. But how was this done? The same person used to be re elected year after year

Digitized by Google

without any inquiry as to his views. The vote was given in a sleepy sort of manner and as a mere matter of form. An alteration had now, however, been effected. Voting papers were sent round and the candidates had to draw up a programme and explain their views. This was a step in the right direction. On the other hand, the Southampton branch of the British Medical Association only meets once a year. It is thought not necessary to meet more frequently because its members are also members of the Southampton Medical Society, which meets every month during the winter season. This purely local society has on several occasions discussed ethical questions and notably the question of club practice. Now as the Southampton Medical Society comprises not only the members of the British Medical Association, but practically all the practitioners of the town, this society seems to be the right centre from which to form a union, a fighting union, whose mission it shall be to defend the economic interests of the profession. Such a union could vigorously take in hand the question of club practice and hospital abuse, and to strengthen its position place itself in communication with the other and similar unions that have been formed in various towns. That there would be plenty of work for such a union to accomplish may be gathered from what has been related above, but more remains to be said.

There is, for instance, the General Hospital known as the Royal South Hants Infirmary. Here already a reform has been accomplished, thanks to the united feeling prevailing in the profession. Formerly all donors to the hospital voted for the election of the members of the medical staff. The majority of these subscribers knew little or nothing concerning the individual merits of the candidates. Now a rule has been passed by which any medical man who canvasses is by that fact alone disqualified to act as a member of the hospital staff. The staff is no longer elected by all the donors; they only elect at the annual meeting a committee of selection composed of five medical men who are out of practice, and therefore less likely to be biased, and ten members of the committee of management, including the chairman and representatives of the medical and surgical staff. A committee thus composed may fairly be considered as competent to judge, for it should possess the necessary personal and technical knowledge to decide judiciously who can best fill any vacancy that occurs on the medical staff.

If the method of selecting the medical staff has thus been reformed, why should not the rules for the admission of patients be also altered and improved? At present, except for cases of urgency and dental cases, all patients must procure a letter of recommendation. This letter contains the terms, "whom I believe to be a fit object of charity," but there is no definition as to what constitutes a fit object of charity. Sometimes a member of the staff may ask the patient himself whether he considers that he is a fit object of charity, and the patient almost invariably answers in the affirmative. There occurred recently, however, a somewhat amusing exception. A young woman presented herself in such a very stylish and elegant dress that the attending physician could not help asking if she thought herself an object for charity. The patient, taken aback by the question, manifested signs of the keenest indignation, protested that she was not an "object" at all, and, deeming that she had been grossly insulted, withdrew with great dignity. Whatever the answer of the patient may be, the medical man has not time, however, to follow up the matter by making investigations at the patient's home, so he is obliged to take for granted all that he is told. Thus there is practically no check, and if a medical officer refuses to take a patient the subscriber who gave a letter of recommendation to the patient will in all probability complain and perhaps refuse to renew his subscription. There can be no question as to the existence of abuse because the subscribers do not themselves make any inquiry before they give recommendations. The fear also of offending the subscribers is so great that on several occasions even incurable cases have been accepted so as not to give offence. One lady recently wanted to withdraw her subscription because the hospital was too full to take in a patient whom she had sent. It has been noticed sometimes that patients who could walk came to the hospital in cabs, thus showing that they were not particularly poor.

Some of the benefit clubs subscribe to the hospital, and therefore conceive that they have the right to send their members as patients even though they may be in very good circumstances. Thus there is a prominent tradesman who belongs to one of these clubs, though he is rich enough to allow his son to keep a cutter yacht. Other well-to-do tradesmen are members of benefit societies and may therefore claim the right to go to the hospital and thus utilise the letters of recommendation which their benefit society obtains in exchange for its subscription. Similar complaints were made at the Eye Hospital. One case was mentioned to me of a man who owns several shops. He went up to the Royal Ophthalmic Hospital at Moorfields, London, but found that he had to wait so long that he transferred his attentions to the Southampton Eye Hospital, where he explained that they had kept him waiting too long in London. It never occurred to this patient that if he could afford to travel backward and forward to London he could afford to pay a fee, and when he was told he ought not to go to a hospital at all, whether in London or Southampton, he replied, "Oh, yes, I ought; they all do it." More than one of the local practitioners told me that several well-to-do people went up from Southampton to the London hospitals. So great, indeed, is the abuse of the hospitals that at a meeting of medical men held some two years ago a "sixpenny doctor" complained that there were more cabs outside the hospital than outside his surgery, and that he had lost many of his patients who, rather than pay him sixpence, had gone to the Eye Hospital, which he thought was as much abused as the General Hospital. Some cases of abuse at the Eye Hospital have, however, been detected and stopped. Thus a little while ago a farmer came. The hospital authorities wrote to the medical man of his village and ascertained that the patient possessed fifty cows, some horses, and several fields. On being told to bring written evidence from his village as to his poverty the patient thought it best not to return to the hospital.

The Southampton Dispensary and Provident Medical Institution does attempt to prevent abuse. According to Rule No. XVII., "no Governor's letter shall be given to a patient the head of whose family is at the time in receipt of more than twenty-one shillings a week, unless the head shall have more than three children under fourteen years of age, or more than four persons dependent upon him, then the limit shall be twenty-five shillings; but the honorary secretaries shall have the power to admit any such case as they may think deserving." This rule of course applies to the charitable work of the dispensaries. The provident members are governed by the following rule: "No member of a family the head of which is in receipt of over thirty shillings per week shall be admitted as a provident member except when the number of children under fourteen years of age exceed three, in which case the limit shall be 35s." Some doubts, however, were expressed to me as to whether this wage-limit was properly applied. It is very difficult to tell when a member has improved his position. A woman the other day confessed that her husband was beyond the limit, so the case was referred to the committee. The practitioner who related this incident to me seemed to doubt whether the committee were well acquainted with their own rule and fully understood its importance. There was a tendency to leave the matter in the hands of the medical men on the ground that it was their business and did not concern anyone else. Though these opinions were expressed by a medical practitioner who had good opportunities of being well informed, they did not harmonise with the views expounded by one of the honorary secretaries of the dispensary on whom I called. He pointed out that the medical men were at liberty to report to the committee any case of abuse that they might observe. Their report remained secret, the committee alone appeared in the matter and it was the committee, and not the medical man which incurred the odium of being accused of hard-heartedness. The committee was very anxious to discover any member whose position had improved, for not only would they strike him off the books as a member, but would press him to become a subscriber. Many members had thus been struck off, but they were unfortunately more prone to write grateful letters for the care they had received in the past than to promise subscriptions for the future. When any complaints were made the committee undertook to institute a full investigation and assumed all the responsibility. If the medical men thought there was still any abuse the honorary secretary earnestly hoped that such cases would at once be brought to the notice of the committee. The wage limit was clearly set forth in the rules, and it was their desire to strictly apply the rule.

Thus it will be seen that at Southampton some good work

Digitized by Google

has been done, some improvements have been effected, and the profession is awakening to a sense of its duties, its dangers, its responsibilities, and the necessity of taking action. But all this is vague and disorganised. The good feeling and the good intentions that prevail must be crystallised in a concrete form. The Southampton Medical Society should take the initiative and establish a Medical Union to defend the material interest of the profession.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Important Prosecutions.

AT Lichfield Police-court, on the 20th inst., a so-called dentist was charged with having obtained 7*s.* from a widow by falsely pretending to be a dentist, and with having, contrary to the provisions of the Dentists' Act, unlawfully, wilfully, and falsely taken and used the name of a dentist. This indictment sounds very emphatic, and counsel on either side sought to make their case good with the usual arguments of such occasions. The upshot was that the magistrates dismissed the charge of false pretences at once; on the second charge the defendant was fined two guineas and costs. It was asked that a special case on the point of law should be granted, and to this assent was given. No doubt this practice is very largely followed, and an authoritative decision will go far to clear the ground of a number of those who constantly contravene the Act to the detriment of unsuspecting and uninformed persons.

Ptomaine Poisoning.

In this instance an action for damages, which constitutes an important precedent, was tried at the Birmingham County Court on the 24th inst. A bricklayer brought an action against a butcher to recover £15 15*s.* for injuries sustained through the negligence of the defendant. It was stated that on July 24th the wife of the plaintiff bought a piece of beef at the defendant's shop; it was requested that it should be pickled, which was done; and it was fetched away the next morning. Plaintiff and his family partook of it, and all were very ill afterwards. The brine in which the meat was alleged to have been placed was examined by a medical man, who pronounced it to be like suds and very filthy—it was said to have never contained any meat. Additional evidence was brought as to the nature of the illness suffered from, and the jury gave a verdict for £3 10*s.* In the interests of the poor investigations of this kind will have a salutary effect in checking imposition and fraud.

Orthopædic and Spinal Hospital.

The Marquis of Hertford presided at the annual meeting of this charity on Oct. 22nd, and drew a grave picture of the financial difficulties which beset the institution. Last year the excess of expenditure over income was £467; this year it has risen to £585, and it was stated that unless some prompt action is taken some of the wards will have to be closed. There were 1563 new cases and renewals during the year, a fact which points to a demand on the resources of the charity. With the large contributions given to the public charities of the town during the present year it would be a reflection on the cause of philanthropy if this useful work had to be in any degree curtailed.

Hospital Sunday.

The Hospital Sunday Fund Collection will be made on the 31st inst., when it is hoped that liberal contributions will be available for the deserving charities whose name is legion in our midst.

Sanitary Inspectors' Conference.

The North-Western and Midland Sanitary Inspectors' Association held a conference at the Council House on the 24th inst. Alderman Cook, chairman of the Health Committee, welcomed them. Various subjects were discussed and grievances ventilated and an amount of useful work got through, unity of action being counselled.

Oct. 26th.

BRISTOL MICROSCOPICAL SOCIETY.—At the fifty-fourth annual meeting of this society, which was held last week, Mr. C. King Rudge, M.R.C.S. Eng., was elected president for the session 1897-98.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Culvert v. Filtration.

THE question of sewage treatment is one of such importance to the country as well as to Manchester that perhaps no apology is needed for reverting to it again. A statement of the difficulties attending precipitation and artificial filtration has been given to the papers by Mr. McDougall, chairman of the Purifying Works Sub-Committee of the corporation, and may be considered official. He says that the process for the separation of the solid matters from the sewage at the Davyhulme works has accomplished all that was expected of it. Precipitation is successfully carried out and a clear effluent passes away from the tanks. This effluent it is proposed to take by underground culvert to the tidal waters of the Mersey. It is not offensive or putrescent, and will not become so if mixed with a sufficiently large body of water containing the free oxygen existing in large rivers or sea water, as oxidation takes place and the organic matter it contains becomes converted into harmless compounds. It is not so, however, when it flows "into the still pool of the Ship Canal between Barton and Irlam Locks," which contains sewage from the large districts above Manchester (and Mr. McDougall might have added from Manchester itself), which is already putrid. "All the free oxygen which would be available in ordinary rivers has been absorbed, and has not been sufficient to oxidise the sewage that has come into it on its way to the city." When, therefore, the effluent enters it decomposition of the organic matter it contains rapidly follows, and if possible the condition of the canal is made worse. The problem is to prevent the effluent becoming putrescent. This has been done at Davyhulme by "passing it through land." An area of twenty-six and a half acres under-drained and specially prepared has been in use from the time the works began operations, "and the filtered water is very excellent." But to deal with 26,000,000 gallons daily 1300 acres would be required, and the committee gave up that idea. Then artificial filters—tanks specially constructed and filled with cinders, coke, or burnt clay—were tried, "upon which the effluent is poured, remaining in contact with the filtering material for a stated period, then drawn off, and the filter remains under the action of the air for about double the length of time it had held the effluent." These experiments were successful as regards the effluent, but after lengthened working it was found that the capacity of the filters became constantly less. This fact and its consequence—the periodical refilling of the filters—had to be considered in forming any estimate of the cost of artificial filtration, which was put down at £275,000 capital outlay for fifty acres of filters, while the yearly interest and sinking fund, working expenses, and refilling every five years were estimated to cost £38,000, equal to a rate of over 3*d.* in the £. The capital outlay for the culvert is put down at £258,000, the interest and sinking fund, with yearly working expenses of £200, at £10,520, equal to a rate of less than 1*d.* in the £. The critics of the culvert scheme consider the estimates for artificial filtration extravagantly high and those for the culvert scheme as much too low. Oldham is now using the land purchased for land filtration for the construction of artificial filters. Salford is making preparations for artificial filtration, and Mr. McDougall naïvely asks, "How can the courts permit Manchester to stop at precipitation when other towns agree to do more?" The corporation is very anxious to get beyond the reach of the Joint Irwell and Mersey Committee, notwithstanding the fact that the chairman of the Rivers Committee is vice-chairman of the Joint Committee and that Sir Henry Roscoe is the adviser common to both. Surely the resources of chemical science are not exhausted with the use of lime and copperas, and Sir Henry Roscoe might venture to draw on them a little further. However the poll may result there is a widespread feeling that the culvert scheme is being rushed and that the Rivers Committee should not have issued almost at the last minute a circular stating that the culvert can be made for less than a penny rate, while artificial filtration will require more than a threepenny rate. Corporation estimates are apt to be exceeded. The Victoria Hotel, built by the Corporation, cost £120,000 when it was only to cost £35,000, and many who have gone into the matter consider that the culvert

Digitized by Google

with all the incidental expenses will require at least £400,000. Last year Sir Henry Roscoe reported that the Davyhulme filters could purify daily 800,000 gallons of sewage per acre, which means that twenty-seven acres of filters would serve instead of the fifty acres of the Rivers Committee. Moreover, filters now working are said to have been in use from twelve to twenty years without refilling, instead of requiring it every five years according to the committee's estimate. The cost of the filters is also said to be put at almost double a fair estimate. The truth is that a sixteen miles culvert to carry away the sewage of 500,000 or 600,000 people is a fine engineering idea jumped at by the Rivers Committee in their panic-stricken efforts to get beyond the jurisdiction of that terrible bogey, the Joint Committee.

Bad Meat in Manchester.

In any large community there will always be more or less waste of food at the hands of the consumers, but small perhaps when compared with what is wasted before reaching them. In a report to be presented to the Manchester City Council on Wednesday the following figures are given with respect to unsound meat, fish, &c., condemned and destroyed under the Public Health Act, 1875, during the year ending Aug. 28th last: meat, 194 316 lb.; fish, 177,287 lb.; shell-fish, 74,344; venison, 592 lb.; hares, 39; grouse, 3; pheasants, 1000; rooks, 73; fowls, 516; ducks, 121; geese, 149; turkeys, 605; rabbits, 2700; and pigeons, 273. In addition to this large quantities of fruit and vegetables of all kinds have been destroyed, among which may be noted 1414 lb. of cranberries, 17 cwt. of cocoanuts, 39 crates of bananas, and 32 barrels of potatoes.

Vegetarian Jubilee Meeting.

The Vegetarian Society held its jubilee in Manchester yesterday week. Representatives were present from all parts of the country and papers were read at the morning meeting by the Rev. Professor Mayor and for Mr. Edmund Baillie on The Bible and Vegetarianism and A Guild of Good Life. During the year fifty-three members and eighteen associates were added to the society, but many old members have been taken away—Sir Isaac Pitman and Mr. Edward Hare, in their eighty-fifth year; Mr. James Parrott, of Manchester and Southport, in his ninety-fifth year; Mr. William Harrison, of Scarborough, at the age of ninety-two years, &c. The report does not name any deaths below the age of seventy-seven years, but we may scarcely assume that vegetarianism ensures life to that age. It appears that the Kayastha Vegetarian Society, India, the 5,000,000 members of which abstain from fish, flesh, fowl, and eggs, is now affiliated with the English society. Mrs. Besant presided at a large public meeting in the evening, and in the course of her speech based her appeal for the system on "the law of life, in other words, the law of love," rather than on the common arguments that it purified the body, so that we were enabled "to have a body that would form less of an obstacle to intellectual and moral growth." A deeper and more attractive reason to her was "that we ourselves were but parts of the one universal life." Many perplexing questions will arise when the multitude begins to put vegetarianism into practice on a large scale.

National Anti-Vaccination League

The annual conference of the National Anti-Vaccination League was held in Manchester last week. According to the reports given in the papers some members of our profession took part in the proceedings. Dr. E. Haughton (London) is stated to have moved a resolution of no confidence in Mr. Carlile's Bill for providing calf lymph, and to have said that "there was no such thing as calf lymph." At the evening meeting Dr. C. Creighton (London) is reported to have moved a resolution in favour of supporting candidates pledged to oppose compulsory vaccination, which was seconded by Mr. Hadwen (Gloucester). This gentleman appears to have said that vaccination was "nothing but a superstition," and to have informed the meeting that "there was not a greater liar in history" than Dr. Jenner.

Oct. 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Professor Macewen and the Glasgow Western Infirmary.

THE fact that the recent re-arrangement of wards consequent upon some change in the staff of the infirmary had caused dissatisfaction in the minds of some of the officials was alluded to in this column last week. It is now public property that Professor Macewen has protested most strongly against the decision of the managers to diminish the number of beds under his care and that the managers have decided to disregard his protest. From obviously inspired statements which have appeared in the press it would seem that for some time there have been differences between Professor Macewen and the managers and that the recent re-arrangements have determined a state of acute conflict. Under the terms of their agreement with the university the managers of the infirmary are bound to provide "reasonable facilities" for the teaching of surgery by the university professor of that subject, and in discharge of their obligations in this respect the managers upon the appointment of Professor Macewen elected him to the staff of the infirmary and placed the wards in his charge. At the same time, they requested him to become responsible for a third ward "as a convenience to the managers," and it is the removal of this ward from his care that has mainly caused the present dispute. The managers at their meeting on the 26th inst. refused to reopen the question, and have issued a statement to this effect to the press. The next step, therefore, rests with Professor Macewen, and it will be awaited with interest. There is a further point at issue between the disputants, which though not immediately urgent will doubtless influence the result of the quarrel. When Professor Macewen was appointed on the staff of the infirmary his dissatisfaction with the existing operating theatre led to his refusal to make use of it. He accordingly has performed all his operations in the corridor from which his wards open, this being specially equipped for the purpose. At the same time he used his influence with the managers to secure the building of three new theatres, which are now rapidly approaching completion. He appears to have considered that one of these theatres was to be reserved for his sole use, and it has been stated that the cost of the erection of one of the theatres was contributed by a Glasgow citizen with this object at Professor Macewen's request. This statement, which has appeared both in the medical and lay press, the managers emphatically deny. They also intimate that whilst no final decision as to the allocation of the theatres has been arrived at, it is hardly reasonable, considering the fact that there are at least six surgeons on the staff, to suppose that they will be able to set aside one of the theatres for the exclusive use of any individual member of the staff. It is thus obvious that there may be serious trouble in the immediate future even should Professor Macewen submit to the decision of the managers to reduce the number of his beds. The unfortunate dispute has to some extent involved the university authorities, as indirectly, if not directly, they have concerned themselves to support Professor Macewen's demands. On the other hand, it must be remembered that the professor of clinical surgery is also a surgeon on the infirmary staff, and as he has taught clinical surgery for many years with only two wards at his disposal he can scarcely be expected to view with favour the contention that for the proper teaching of the subject three wards are required; further, the gentleman who, it is suggested, shall share the operating theatre with Professor Macewen, is also a member of the University Senatus, and no one can be surprised that Professor Macewen's objection has thus given rise to some personal feeling. Altogether the dispute is a very unfortunate one, and is exciting much comment in medical circles. The stage for private conference and mutual concessions seems to have been passed since the disputants have come into the public prints. But it may be hoped for the sake of the school of surgery in Glasgow that some arrangement may yet be arrived at, though the method of this it is at present difficult to perceive.—Two new appointments to the staff of the Glasgow Western Infirmary are intimated—viz., Mr. Ralph Stockman, M.D. Edin., to be visiting physician; Mr. J. Crawford Renton, M.D. Edin., to be visiting surgeon. Dr. Stockman is to have charge of the beds reserved for the "clinical teaching of materia medica and therapeutics."

New Infectious Diseases Hospital for Lanarkshire.

The new hospital for infectious diseases which has been built near Motherwell by the district committee of the middle ward of Lanarkshire was opened on Oct. 25th. This hospital is the fifth which has been provided by the district committee to meet the needs of the middle ward of the county. The site extends to about six acres of elevated ground looking over the Clyde valley. There are beds for 100 adult patients, the ward accommodation being four

Digitized by Google

pavilions of twenty beds each, eight private wards of one bed each, one isolation pavilion of six beds, and one observation pavilion of six beds. The resident staff provided for consists of a medical officer, a matron, sixteen nurses, six maid servants, and a male attendant at the lodge. The main wards have their long direction north and south, thus securing exposure to the sun's rays during the whole day. Each pavilion is divided into two wards containing ten beds. The main wards are 60 feet long by 26 feet wide and 13 feet high, giving to each bed 12 feet of linear wall space, 156 square feet of floor space, and 2028 feet of cubic space. The floors are of pitch pine, wax polished, and the walls and ceilings are finished in Keene's cement. The sewage is purified before leaving the hospital grounds, two tanks and filters having been constructed for the purpose. The mortuary has a small room from which relatives can view the dead through a glazed opening. The cost of the hospital, including all fittings, apparatus, machinery, furniture, and fees, will be about £37,000, or £370 per bed.

Oct. 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Royal University of Ireland.

THE annual meeting for conferring degrees of the Royal University was held in the large hall of the institution on the 22nd inst. It was attended with more than usual interest, the Marquis of Dufferin, Chancellor of the University, presiding and the Senate being largely represented. Among the Senators were the Right Hon. Christopher Redington, Vice-Chancellor; the Earl of Kenmare, K.P.; the Earl of Rosse, K.P., LL D., F.R.S.; and the Right Hon. Lord Morris. The President delivered a most interesting and graceful address, at the conclusion of which he complimented certain members of the University on whom honorary degrees were about to be conferred. The list included two medical men—Dr. Whitla, Professor of Materia Medica and Therapeutics in Queen's College, Belfast, who received the degree of M A *honoris causâ*, and Dr. Byers, Professor of Midwifery in the same institution, who obtained the degree of M.A.O. *honoris causâ*. At the same time the degree of D.Sc. *honoris causâ* was conferred upon Dr. Divers, formerly a scholar of Queen's College, Galway, and now Professor of Chemistry in the University of Japan, and upon Mr. W. E. Adeney, F.I.C., F.C.S., the Curator of the Museum of the University, in recognition of the scientific value of their work. Mr. Adeney's doctorate had special reference to his labours with regard to the bacterio-chemistry of sewage.

Funeral of the late Mr. O'Grady.

The funeral of the late Mr. E. Stamer O'Grady, M.A., M.B. Dub., F.R.C.S. Irel., which was strictly private, left Merrion-square on the morning of Oct. 22nd for Kingsbridge terminus, arriving at Limerick junction at 11.30 A.M. From the junction the remains were conveyed to the family burial ground, near Kilballyowen, the ancient seat of "The O'Grady" family.

Typhoid Fever at Ligoniel.

A serious outbreak of typhoid fever has occurred at Ligoniel, a village on the northern outskirts of Belfast. Since Oct. 6 h the dispensary medical officer has had visiting lines presented for 32 cases of typhoid fever, and 21 or 22 have come in since Oct. 18th. A special meeting of the board of guardians was held on Oct. 22nd to consider the matter. The general impression is that the sewerage of the district is defective, and that the water-supply is at fault. Indeed, Dr. Clibborn (Local Government Board inspector) stated at the meeting that "the sewerage—indeed, it could be hardly dignified with the name of a system—system was very bad." It was decided to issue handbills and posters in the district giving the inhabitants simple directions as to keeping the houses strictly clean, keeping articles of food and drink in proper condition, and boiling the milk and seeing that the vessels in which it was kept were scrupulously clean. It was also arranged to supply the inhabitants with disinfectants and to have a bacteriological examination of the water made. On Nov. 25th Ligoniel, according to the new Act, will become part of Belfast and the corporation will have to deal with the sewerage question.

Typhoid Fever in Belfast.

At present (Oct 23rd) there are 17 cases of typhoid fever in the Royal Hospital and 142 in the Union Hospital. During the four weeks ended Oct. 20th 354 cases of typhoid fever (a decrease of 25 on the returns of the previous four weeks) were reported. The epidemic is most prevalent in the Shankhill and Ballymacarrett districts, but there are cases all over the city. The mortality is not high so far.

Ballymena Water supply.

The inhabitants of Ballymena are entitled to have 200 000 gallons of water per day from the Quoile reservoir, but through incrustation of the pipes they now actually only receive 172 000 gallons. As a result the supply is an intermittent one, and they propose to construct a line of 8-in. instead of 5 in. pipes between the River Quoile and the filter-beds, a distance of two and three-quarter miles. For this work £2600 is required, and it is proposed to borrow £3000 from the Local Government Board.

The Cork Medical and Surgical Association.

The annual dinner of the Cork Medical and Surgical Association was held last Saturday night. There were about fifty present, including members and guests. The chair was occupied by Mr. Philip Lee, President of the Association, and Dr. Edward Magner, Vice-President, was in the vice-chair. There were numerous toasts and songs, and a most enjoyable evening was spent. These re-unions tend to bind the members of the profession together, and to establish an *esprit de corps*, especially valuable whilst the club question is before the public.

Outbreak of Diphtheria at Monkstown, County Cork.

There were several cases of diphtheria recently in the neighbourhood of Monkstown, a seaside resort near Cork. The sanitary authorities have gone to work with energy and no new cases have been reported during the past few days. It is suspected that defective sewers may have been the originating cause, and the engineer to the board of guardians has been instructed to make a thorough investigation and to at once adopt any measures he may find requisite.
